Federal Infrastructure Strategy Program

June 1994

IWR Report 94-FIS-10

Federal Infrastructure Strategy Reports

This is the tenth in a series of interim documents published by the U.S. Army Corps of Engineers during the Federal Infrastructure Strategy program, a three-year effort to explore the development of an integrated or multi-agency Federal infrastructure policy. This report documents and describes a model known as the Local Public Finance Impact (LPFI) model which estimates the impact that a proposed infrastructure project will have on local government revenues and expenditures.

Other reports in the series thus far include:

Framing the Dialogue: Strategies, Issues and Opportunities (IWR Report 93-FIS-1);

Challenges and Opportunities for Innovation in the Public Works Infrastructure, Volumes 1 and 2, (IWR Reports 93-FIS-2 and 93-FIS-3);

Infrastructure in the 21st Century Economy: A Review of the Issues and Outline of a Study of the Impacts of Federal Infrastructure Investments (IWR Report 93-FIS-4);

Federal Public Works Infrastructure R&D: A New Perspective (IWR Report 93-FIS-5);

The Federal Role in Funding State and Local Infrastructure: Two Reports on Public Works Financing (IWR Report 93-FIS-6)

Infrastructure in the 21st Century Economy: An Interim Report - Volume 1 - The Dimensions of Public Works' Effects on Growth and Industry (IWR Report 94-FIS-7); and

Infrastructure in the 21st Century Economy: An Interim Report - Volume 2 - Three Conceptual Papers Exploring the Link Between Public Capital and Productivity (IWR Report 94-FIS-8).

Infrastructure in the 21st Century Economy: An Interim Report - Volume 3 - Data on Federal Capital Stocks and Investment Flows (IWR Report 94-FIS-9).

The program will culminate with a summary report to be published in 1994. The interim documentation contained herein is not intended to foreclose or preclude the program's final conclusions and recommendations. Within this context, comments are welcome on any of these reports.

For further information on the Federal Infrastructure Strategy Program, please contact:

LOCAL PUBLIC FINANCE IMPACT MODEL: USER'S GUIDE AND TECHNICAL DOCUMENTATION

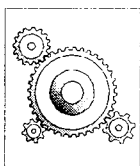

ACKNOWLEDGEMENTS

The Local Public Finance Impact (LPFI) Model is a working prototype of a system which can be used by public managers to predict the potential changes in local revenues and expenditures caused by public infrastructure investments. The principal investigators for the effort and principal authors of this document were Dr. Dennis P. Robinson of the Navigation Division of IWR and Dr. Harry H. Kelejian of the University of Maryland at College Park. Both investigators worked out of the Navigation Division of IWR, headed by Dr. Lloyd G. Antle.

The prototype was developed as a component of the Corps of Engineers Federal Infrastructure Strategy (FIS) Program. The FIS program is managed by the Institute for Water Resources (IWR) under the direction of Mr. Kyle Schilling, Director of the Institute. The LPFI study component was managed by Dr. Cameron Gordon, Economics Study Manager who also edited the final report and wrote much of Chapters 3 and 4. The director of the overall FIS program is Mr. Robert Pietrowsky.

Special thanks goes to Mr. Kim M. Bloomquist (Chief of the Economics Branch) of the U.S. Army Engineer District at Chicago for the summary of the current fiscal impact practices (conventional and models). Special thanks also goes to Mr. Ronald D. Webster at the U.S. Army Construction Engineering Research Laboratory (USA-CERL) for the use of the Economic Impact Forecast System and its databases.

LOCAL PUBLIC FINANCE IMPACT MODEL: USER'S GUIDE AND TECHNICAL DOCUMENTATION

1. OVERVIEW AND EXECUTIVE SUMMARY

This report documents the development and implementation of a model to estimate the effects on local public revenue and expenditures which would be expected to stem from the construction and operation of an infrastructure facility (such as a lock and dam or a highway). To accomplish this purpose reliably, and to be of the most use to the relevant audience of local decisionmakers, the model was specified to have certain characteristics. The model was to be locally focused, i.e., estimate revenue and expenditure impacts at the county level. The model was to account for the inter-jurisdictional benefit spillover effects, namely the revenue and expenditure effects resulting from the public facilities in one jurisdiction being used by residents in other, nearby or adjacent communities. The model was to be implemented in conjunction with an existing regional economic impact model. The model would have to be generic enough to be used in conjunction with a variety of regional economic impact models (such as economic base, input-output, and econometric). Finally, the model would have to be relatively easy to use and accessible to a wide range of users.

With these objectives in place, the Local Public Finance Impact (LPFI) model prototype has been developed. It is a fully operational model which, as currently configured, does estimate county-level public revenue and expenditure impacts in a way that accounts for inter-jurisdictional benefit spillover effects. The prototype is currently integrated into a broader impact forecasting model known as the Economic Impact Forecasting System (EIFS) which is currently available for use on the OSIRIS computer system at the U.S. Army Construction Engineering Research Laboratory (USA-CERL) located at Champaign-Urbana, Illinois via a computer modem using an 800-number dial-in access. While the LPFI prototype is presently a module added in to EIFS, it is generic enough to be used with most, if not all, regional economic impact models available at the time of this writing.

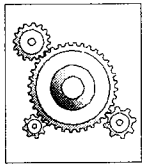

This report summarizes the LPFI model, its general characteristics, and its use. The report includes specific user instructions for the access and use of the EIFS/LPFI model combination. Four hypothetical case studies are provided. The traditional or conventional methods of computing fiscal (i.e., revenue and expenditure) impacts by planners are reviewed, and several available, competing fiscal impact models are discussed and evaluated. Finally, the report provides technical documentation concerning the LPFI model's logic, econometric structure, statistical estimation methodology, and performance evaluation.

This research effort also assessed the predictive performance of the model. When the LPFI and EIFS models are run to produce estimates of revenues and expenditures for past time periods and those estimates are then compared with the actual historical record, the EIFS model revenue predictions are about 100 percent (%) higher in comparison to the historic record than those of the LPFI model and the expenditure impacts are about one-third higher. This conclusion seems to hold regardless of the perspective that one uses to compare the resultant revenue and expenditure predictions (i.e., by state, by BEA economic area, or by metro or non-metro area).

This model is a prototype and as such further development is desirable to make the fruits of this effort more widely disseminated and used. On the modelling side, given the interrelationship between LPFI and EIFS, and given that LPFI appears to significantly improve forecasts of public revenue and expenditure changes caused by infrastructure investments, a more complete integration of LPFI into EIFS is warranted. In addition, the predictive performance of LPFI should be assessed against other regional economic impact models, such as econometric and input-output structures to evaluate its overall "robustness".

As for the user interface, it is recommended that a PC-compatible "stand-alone" version of LPFI be developed since PC platforms are generally more accessible than the mainframe platform on which EIFS currently resides. In addition, more comprehensive user documentation covering the use of LPFI in conjunction with other forecast models and providing more details on running the model and interpreting its results should also be developed. "Beta-testing" of both the model and its documentation would be useful, particularly as part of an undergraduate or graduate class in public finance. Such a more refined model would find broad use within the Corps. There is also a need for this model to be included in agency training courses, with perhaps a course specifically devoted to LPFI use itself.

LOCAL PUBLIC FINANCE IMPACT MODEL: USER'S GUIDE AND TECHNICAL DOCUMENTATION

2. FISCAL IMPACT ANALYSIS AND THE LOCAL PUBLIC FINANCE IMPACT MODEL

INTRODUCTION

Infrastructure projects generate many effects through their construction and operations. They require the employment of workers, who are paid, and with new workers often migrating and bringing their families due to the employment opportunities, etc. Along with these effects, these projects are also expected to alter the needs for local public services and, as a consequence, to change the requirements for revenues in order to pay for the new levels of services. These broad revenue and expenditure effects are important in the initial stages of planning, when program managers are making initial budget allocations. It would be useful to have an analytic tool to aid in this process. The LPFI model was developed to estimate these types of local public revenue and expenditure impacts of infrastructure developments.

WHAT IS THE LOCAL PUBLIC FINANCE IMPACT MODEL?

The Local Public Finance Impact (LPFI) model is a set of empirical equations that, when used in conjunction with an existing regional economic impact model (such as an input-output model), will estimate the local government revenue and expenditure effects which stem from a proposed project or action. Regional economic impact models are tools used by economists, regional analysts, and other professionals to estimate the consequences of projects, programs, actions, and policies (in terms of their associated income, employment, business sales, population effects), usually within communities surrounding the projects or parts of the country that are most directly affected by the programs, actions, or policies.

WHY IS IT CALLED "PUBLIC FINANCE" IMPACT MODEL?

"Public Finance" in this context is used to refer to the finances -- revenues and expenditures -- of public entities -- local governments -- and the way in which those finances are affected by infrastructure investments. Public finance as used here does not refer to financing requirements for a project (e.g., how much a project costs or what methods are used to raise the necessary funds); the LPFI model is not intended to generate, and cannot generate, this information which must be provided by the user.

WHAT DOES THE LPFI MODEL DO?

The LPFI model estimates the local government revenue and expenditure consequences of a change in the economic and demographic character of a local economy. The LPFI model estimates impact estimates for five (5) categories of revenue:

- Federal transfers
- State and local transfers
- Local taxes
- Charges and miscellaneous revenues
- Utility, liquor store, and insurance trust revenues;

and ten (10) categories of expenditures:

- Education expenditures
- Health and hospital expenditures
- Transportation expenditures
- Police protection and corrections expenditures
- Fire protection expenditures
- Natural resources, parks, and recreation expenditures
- Public welfare, housing, and community development expenditures
- Sewerage and sanitation expenditures
- Government finance, administration, and general expenditures plus interest on the debt
- Utility, liquor store, and insurance trust expenditures

These categories correspond to the major categories used in collecting data for the Census of Governments collected by the U.S. Bureau of the Census. These categories indicate the types of revenues and expenditures collected by State and local governments. Of course, in some areas, some of these categories do not apply. For example, only some States operate public liquor stores and only these States would raise any liquor store revenues.

All categories of revenues and expenditures are computed in per capita terms, except tax revenues (which are computed relative to local personal income) and education expenditures (which are computed on a per student basis).

WHAT THE LPFI MODEL DOES NOT DO

As mentioned in a previous section, the LPFI model does not estimate how much a project is going to cost; the financial requirements necessary to implement a project must be estimated and provided by the user of the LPFI model as an input.

What the LPFI does do is estimate how a project, once paid for, will affect revenues and expenditures of the community's government. This output is important for many reasons, not least because many proposed projects are implemented on the grounds of future revenue streams; for example, sports stadiums, gambling facilities, or tax incentives to attract business establishments are often sold to the public on the grounds of future employment opportunities and revenue sources. However, often there is little evaluation of or even reflection on the reality of these prospects. The LPFI model is meant to help fill this gap.

WHO SHOULD USE THE LPFI MODEL?

It is not required that a potential user of the LPFI model be a subject matter expert either in regional economic impact analysis or in fiscal analysis. A user of the LPFI model is expected, however, to have a basic familiarity with both regional economic impact models and local public finance (fiscal) analysis.

Fiscal impact analysis (FIA), as used in this report, is simply a procedure or set of procedures for determining whether a proposed infrastructure development in a community will generate sufficient revenues to offset the associated expenditures. FIA is not a new concept. Planners have used the technique for more than forty years to evaluate the local fiscal effects of public housing, urban renewal programs, and the suburbanization movement, to name a but a few applications (Mace, 1961). More recently, FIA has been used to assess the revenue and expenditure impacts of redeveloping older suburbs (Listokin and Beaton, 1983), developments adjacent to a major transportation corridor (Office of Economic Policy, 1986), and large-scale defense projects (Lienesch, Ambargis, and Kort, 1987).

It should be noted that fiscal analysis is a broad study of the direct and indirect effects that a project will have on a community's public revenues and expenditures. Thus it is more wide-ranging than an investment analysis which tends to focus solely on the effectiveness of investment mechanisms, such as borrowing versus tax finance, in financing a given project.

There are several excellent sources for regional economic impacts analysis: for example, see Hoover (1975), Nourse (1968), Richardson (1979), and Treyz (1993). Aronson and Hilley (1986), Beaton (1983), Prudhomme (1986), and Rosen (1986) provide coverage of the major issues concerning local public finance. Burchell, Listoken, and Dolphin (1985) demonstrate practical suggestions for computing fiscal impacts. Wildasin (1986) explains the many of the theoretical concepts used by public finance analysts.

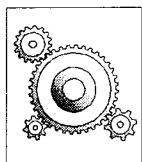

HOW IS THE LPFI ESTIMATED?

The LPFI model was estimated using a cross-section of data at the county level over the entire United States (approximately 3,100 county units). This means that the LPFI model should provide reasonable revenue and expenditure impact estimates anywhere in the country.

ASSUMPTIONS AND LIMITATIONS OF THE LPFI MODEL

The LPFI model assumes that public administrators and local legislators raise revenues to provide public services in order to satisfy their constituents' demands for those public services. It is also assumed that local revenue and expenditure decisions are determined by what public officials think their constituents want. The levels of public services and revenues that public officials expect that their constituents want is determined by a number of demographic, economic, and fiscal characteristics within the community, including the array of public services and revenues found in neighboring communities. Changes in any of these factors are likely to alter public officials' thoughts concerning their constituents' desires for public services and, in turn, change the levels of public expenditures and revenues. It is also presumed that the economic and demographic changes stem from the effects of a project or program in an area (for example, due to the construction of lock and dam or from the operations of a local retail or manufacturing plant).

LOCAL PUBLIC FINANCE IMPACT MODEL: USER'S GUIDE AND TECHNICAL DOCUMENTATION

3. A USER'S GUIDE FOR THE LOCAL PUBLIC FINANCE IMPACT MODEL

PLATFORM AND ACCESS

The LPFI model currently operates on the computer system run by the University of Illinois for the U.S. Army Construction Engineering Research Laboratory (USA-CERL) in Champaign-Urbana, Illinois. USA-CERL is the platform for a number of user applications, including an economic impact forecasting system known as the Economic Impacts Forecasting System (EIFS). EIFS is what is known as an economic base model (see chapter 5 for a definition) which estimates direct and indirect changes that ripple through the economy when a change, such as a new construction project, is introduced. EIFS also contains an extensive economic and demographic database which it uses to project future economic impacts.

LPFI is an independent module attached to the EIFS model. Thus when the user provides estimates of how much, say, a new dam will cost and how much labor and capital it will require, it is the EIFS model which provides the historic record of the economy of the region affected and which then estimates how this new investment will affect the flows of goods and services in and out of that region. The LPFI model then uses these results to estimate how the initial investment, as altered by the economic changes it induced, will affect public revenues and expenditures, broken down by the detailed categories described earlier. While LPFI does require basic economic and demographic data and estimates of spending "multipliers" which represent changes in economic flows induced by a project, it does not require EIFS to provide these data and estimates. Rather EIFS is an accessible and powerful tool well suited to developing the LPFI prototype. LPFI is completely transportable for use with other models and can even be used alone as long as the user provides some basic information beyond the requirements of the project itself.

Access to the USA-CERL computer system and to the EIFS/LPFI model is available via telephone modem or other communications link with the computer through an 800 telephone number. To use the LPFI model, the user first must register with staff of the Environmental Technical Information System (ETIS) at USA-CERL to obtain a "login" name to access the USA-CERL computer. Instructions for using the USA-CERL computer, login-registration, and an EIFS User's Manual can be acquired via telephone at 1-800-USA-CERL. The conditions and costs of obtaining a login name will vary by type of user. Because the U.S. Army Corps of Engineers has provided some funding for development of EIFS and other USA-CERL applications, Corps employees generally can obtain a login at no cost. Users outside the Corps will generally have to pay for an account. Instructions for using the EIFS program are found in the EIFS User's Manual. The instructions provided here only explain how to use the LPFI model component of EIFS.

INVOKING LPFI

Here are the steps that a new user would have to take to call up the LPFI and get it ready to run:

1. Call USA-CERL and obtain an account as described above.
2. Using a modem, dial up the CERL computer and log in, providing your log-in name and password.
3. The user will then be presented with a menu of options. Choose the menu option numbered "4" which is called "Expert". This option will get you to the system-prompt of the computer. This is analagous to turning on your PC and going straight into the DOS operating system where one usually sees a symbol like "C:\\" and where instructions can then be entered. Once you have selected this option, you will be faced with a blank screen and a prompt that will appear similar to the following: "yourname/osiris/home/1>".
4. At this prompt, type the following command

[1] ***~robinson/bin/LPFI filename <CR>***

This command is made up of two parts: the command and the file name. The command is the first part (***~robinson/bin/LPFI***) and the file name is the second part (***filename***). ***<CR>*** is the return or enter key. The command part must be typed as is shown above. The file name part can be any character or combination of characters the user cares to use. It is suggested that the user may want to consider file names that have logical or contextual meaning. For instance, the file name could be a reference to a project or a particular project scenario.

The ***filename*** is necessary in the above command because the computer operating system at USA-CERL does not have "screen-saving" capabilities. In other words, once results are generated, they will be printed on the screen all at once. While it is possible to interrupt this printing, it is not possible to review the results without running the model again. It is possible, however, to save the results to a file and then scroll through them later, either on the USA-CERL computer itself or on the user's own computer after the file has been down-loaded (that is transferred from the USE-CERL computer via the modem). Instructions on downloading files are available from CERL, or from documentation with your modem or communications package.

RUNNING LPFI

Once LPFI is invoked, the EIFS system and its interface takes over. The user operates the EIFS program just as it is described in the EIFS User's Manual. The four examples which are provided later on will provide all the user needs to know to run LPFI. As these examples show, running the model is fairly straightforward.

First Step - Defining the region: After invoking the EIFS/LPFI command, [1], above, EIFS will ask the user to define the region of influence (ROI). This will be the geographic area where most the economic, demographic, and fiscal impacts are expected to occur.

How does one decide to define the region that is the geographic setting for socioeconomic/fiscal impact analysis? For people not accustomed to carrying out regional analysis, justifying a particular study area may not be easy. Even among experienced regional analysts, delineating a study region is a thorny, but very important issue. Unfortunately, few universally accepted rules are available to help an analyst choose at study area. Thus, the regional definition for an impact analysis is usually somewhat subjective or arbitrary. See Appendix A for a number of useful suggestions for defining regions.

Defining the ROI in EIFS is accomplished in one of two ways. First, the user may simply type in one or more county names when prompted by the EIFS program. Thus if the user knows exactly which counties will be affected by a project, the county names, along with their corresponding State locations, can be typed in directly. For example, a project in New York City which affects only the borough of Manhattan will have an ROI encompassed by "*new york, ny*", "new york" being the county of New York, and "ny" being the State of New York. Other ways of defining regions are available on the EIFS system. For example, a user is able define a region by using any of the Metropolitan Statistical Areas (MSAs), Bureau of Economic Analysis Economic Areas (EAs), or predefined military installation regions.

The other way which the user can define a region is to pick a radius centered around a particular county. If a project will impact the City of Chicago and surrounding areas, a user can define a region by invoking the command

[2] *radius of cook, il* <CR>

EIFS will ask the user for the distance he/she wants to use. This effectively defines a region by drawing a circle (by computer) around the location in question. If the user specifies a 50-mile radius (as specified in the example given in Figure 1), then the computer will include the Cook county and the 10 counties surrounding it as the ROI, if the user so desires (the computer gives the user the option of including or not including these surrounding counties). Finally, EIFS will allow a user to predefine a region.

Figure 1 provides a sample of the initial sequence of prompts and commands which ensue after invoking LPFI. The output presented above may not exactly match the output the user sees in the future as the USA-CERL system continues to be improved. The bold-faced characters above indicate what the user puts in. First the ROI is entered, in this case the radius around Cook county ("*radius of cook, il*"). The user is then asked for the radius desired in miles. In this case, "50" is entered for 50 miles around Cook county, Illinois. 10 counties fall within this radius and the user is given the choice of including all of them. Then, when prompted for the next region, the user simply pushes their return or enter key ("<CR>"). If the user had wanted to expand the ROI to include other radii or other counties, then other county names or radii would have been specified. The computer would keep prompting the user for names and would keep accepting input from the user until a carriage return was entered.

The next message - "aggregating data..." - indicates that EIFS is collecting the necessary data for the ROI so that LPFI can do its calculations. With all of the counties chosen and data aggregated, the "multipliers" for the county list are calculated; these multipliers are estimates of the changes in spending which will take place within a region when a dollar of new spending is introduced or removed. A summary of options for displaying the output that LPFI will ultimately provide is then presented. These options are not discussed here.

Economic Impact Forecast System - Version 5.0

First county or region (type ? for help): *radius of cook, il*

Find counties within what radius (miles)? *50 <CR>*

Found 10 counties - add them to your list? (y/n): *y <CR>*

Next county or region (type RETURN if done): *<CR>*

aggregating data...

1987 multipliers are being calculated for your list (10 counties).

OUTPUT WILL BE SHOWN AS: Tables, Not-Paged, with Footnotes

You may change these by asking for "f" at the "what section/profile" prompt

Figure 1 - Defining a Region in EIFS and LPFI

Finding the EIFS forecast models: After choosing the ROI, the user is presented with options for choosing the type of forecast model they want to use. These forecast models are the EIFS models which estimate economic changes induced by given types of projects. Figure 2 summarizes the prompts and commands that a user would be faced with.

What is happening here is that the user is being offered a choice of different EIFS forecast models and data. The EIFS forecast models are found in the "models" sub-menu. To get there, a user must ask for the models sub-menu when the EIFS system asks the question

[3] **EIFS v5.0 - What Section (<cr> to see list):**

at the "Main Menu" level (as is shown at the top of Figure 2). If the user wants to see a list of options, the he/she would enter a carriage return (<CR>) at the Main Menu level.

Note that the last message - "incomplete data for proportion of children in school" - simply indicates that data for this particular set of data, not having been provided by the user, is incomplete. It will not affect the model run and is provided simply for the user's information.

The EIFS forecast models are found in option 1 of the models sub-menu. The EIFS system will automatically list the menu for the user to see. Other model options are available to the user, however

they are not integrated with the LPFI model. If they are run, then this will cause an error in the LPFI model program. A "core dump" will occur and the user may get a call from the USA-CERL staff. If a core dump does occur, just delete the core file by typing

[4] *rm core <CR>*

Running the EIFS forecast models: After defining the region of influence and after finding the forecast models profile within the EIFS system, the user is faced with running a forecast run. This will involve choosing a forecast model and answering a series of questions that will describe the project or action for the EIFS program.

There are five versions of the EIFS forecast models. Each version analyzes a specific impact scenario.

- Standard EIFS Forecast Model
- Construction
- Construction of On-Base Housing
- Training
- AR 5-20 Economic Effects Analysis

For most purposes, however, only two of the EIFS forecast models will be relevant.¹ One, the Standard EIFS Forecast Model is appropriate when the contemplated project is an expansion or contraction of present operations. This could mean a closure or opening of a facility or simply a scenario of continued operations. And two, the Construction EIFS Forecast Model is used when the construction of a facility is planned. This model also applies in those cases where periodic maintenance is required.

The inputs required from users include those data necessary to describe the project. Specifically users must provide:

1. year in which the analysis is conducted,
2. number of project-specific civilians workers and their average annual salary,
3. percent of workers that will migrate in or out of the region as a result of the project action,
3. total local project-specific expenditures (excluding worker wages and salaries) that support the project, and

¹The other three models are for specific military actions and don't have general civilian application.

if military personnel are involved,

4. number of military affected and their average annual salary, and
5. percentage of military living on-post.

The system will provide default values for most of these categories if the user does not have them available.

In Figure 3, an example of a Chicago construction project is offered to demonstrate the sort of input the user must provide along with the sort of output that LPFI generates in response.

Note that the user enters a carriage return ("`<CR>`") to obtain the model menu. Since this is a construction project, the user enters "2", followed by a carriage return ("`<CR>`") to use the construction forecasting model. A name for the project is provided - "Construct a Chicago Office Building" - and, unless the user has their own price deflators, a "`<CR>`" will trigger the use of deflators provided by the model as a default. These values are then shown on the screen and the user is asked to input either total expenditures on the project (in areas within the ROI and outside of it) or just local expenditures. In the example above, local expenditures are chosen and estimated by the user to be \$100,000,000. Default values for the percentage of those expenditures going to labor and materials and for the percentage of the construction labor force working on the project expected to migrate in from outside the ROI are all accepted by typing in a series of "`<CR>`"s at the appropriate prompt. Then the model prompts the user to enter another forecast model, but in this case, no new runs are desired and, the user simply types "quit" followed by a "`<CR>`" to get out of this menu and start the model running. Although not shown above, the user is then returned to the OS prompt, shown a message saying "FORTRAN STOP" indicating that the model run is complete and the results are ready for examination. Entering another "`<CR>`" and this point will leave the user free to start another run, or enter other system commands.

Note that the year in which the impact is to occur is necessary to establish the appropriate adjustment to dollar figures in the model, using such tools as consumer price indices. The average annual salary data is necessary to describe the total salary inputs to the local region which are affected. Salary is defined as gross income (which is pay before deductions for income tax, withholding, and social security tax, but does not include retirement and other benefits that are not received directly by the employee).

Special pay categories for the military personnel (such as "jump" pay, "diving" pay, or "flight" pay) and housing allowances should also be included in the salary computation. The dollar value of local expenditures is the total annual change in project-related expenditures for two categories: 1) goods and services and 2) construction labor plus construction materials. Goods and service expenditures are used in the Standard EIFS Forecast Model and construction expenditures, of course, are used in the Construction EIFS Forecast Model.

Figure 3 - Running the Construction EIFS Forecast Model

The EIFS Forecast Models produces a number of impact estimates. The model produces the following output:

1. change in total local sales volume,
2. change in total local employment,
3. change in total local income, and
4. change in total local population.

Sales volume measures the change in local total economic activity resulting from the project. Employment measures the number of "full-time" jobs affected by the proposed action. Income is measured in two ways; "place of work" and "place of residence." "Place of work income" is the amount of income generated in the region of influence due to the action by people who work in the region. "Place of residence" income is the amount of income generated in the region of influence due to the actions of people who actually reside in the region. Population is the number of people who migrate in or out of the region as a result of the proposed project.

Just to provide an example of how the a project where only new staff is hired, rather than where new construction takes place, Figure 4 shows the user instructions and computer output which results when running the Standard EIFS Forecast Model rather than the Construction Model. The logic for interpreting Figure 4 is the same as that for interpreting Figure 3.

Viewing the LPFI/EIFS output: When finished with the EIFS/LPFI run, the user just types in the command, *quit <CR>*, on the EIFS command line. This will disconnect the user from the EIFS program and operate the LPFI program. The user does not have to do anything but wait the second or two it takes for the LPFI program to run. The LPFI program will put its results in the file named by the user (i.e., filename). After that, users will want to download the file to their own computer and then log off the CERL mainframe. The user may also scan the results of the model run immediately by typing *show filename* at the prompt. This command will allow the user to see the results one screen at a time and will allow the user to scroll through them backwards and forwards. Once again, details on logging off and downloading are readily available from the documentation obtained after having opened a CERL account.

OTHER USES OF THE LPFI MODEL

The Local Public Finance Impact model can be used with a variety of regional economic impact models. These models are generally classified by type according to the methodology used to compute the impacts; e.g., input-output, econometric, and small-area assessment.² Most of these models generate, as a minimum, impacts in the categories of output (or sales), employment, and income. Some regional economic impact models (especially the econometric models) also generate population, labor force, and housing impacts.

²Bolton (1985), Hoover (1975), Nourse (1968), Richardson (1979 and 1985), and Treyz (1993) provide excellent discussions of the characteristics and attributes of regional economic models.

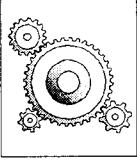

Figure 4 - Running the Standard EIFS Forecast Model for use with LPFI

To combine the LPFI model with any of the existing regional economic impact models care must be taken to appropriately configure the impacts that go from the regional economic impact model to LPFI. Appendix B provides a list of explanatory variables that if changed will cause LPFI to estimate consequent changes in revenues and expenditures. It is important that all monetary changes should reflect price levels for 1982. Also, most regional economic impact models generate their values in terms of changes. For such models, the LPFI equations variables related to the state-specific effects (i.e., state "binary" variables) can be ignored.

The LPFI model can also be used as a "stand-alone" public finance impact model. This would be useful for simulation analysis. For example, a proposed residential development may provide for 300 single-family dwellings, for 1,000 townhouses, or for a retirement community housing 2,500 people (depending on the type of zoning applied to the development). The estimated revenue and expenditure impacts will vary significantly with these scenarios and their associated demographic and economic characteristics.

LOCAL PUBLIC FINANCE IMPACT MODEL: USER'S GUIDE AND TECHNICAL DOCUMENTATION

4. CASE STUDIES USING THE EIFS/LPFI MODEL

To provide more detail of the mechanics of the EIFS/LPFI model, four case studies were analyzed: a construction project in Southern Illinois; a staff reduction with a contract replacement in Los Angeles, California; opening a new Corps of Engineers office in Los Angeles; and a reuse function for Chanute Air Force Base in Illinois. The results from these case studies are shown in Figures 5 through 8 and discussed below.

CASE 1: CONSTRUCTING A FLOOD CONTROL PROJECT IN SOUTHERN ILLINOIS

The first case study (Figure 5) is that of a hypothetical proposed construction project located in an area of the southern-most part of the State of Illinois. The proposed project is the construction of a small flood control project. It is assumed that the exact size and operation of the proposed facility is not known due to the early planning phase of the project. However, the State legislature and local county officials want to know the nature of the economic and fiscal impacts that the project will place on the local communities near the proposed facility. In order to determine a reasonable estimate of these impacts, it was decided to hypothesize a \$10 million construction project. In addition, the State legislature specifies that the construction funds are to be spent within the area of Jackson and Union Counties of Illinois due to historically high unemployment problems in the southern part of the State. Figure 5 shows the results of the LPFI/EIFS model run. The first part of the model output simply shows the inputs provided either by the user or the computer if a default value was used. Basic demographic and geographic information is shown for the counties which make up the ROI, in this case Jackson and Union counties in Illinois. Below that the "functional area" indicates that the option "2" - the construction model - has been employed. The project name as designated by the user is then shown, followed by the price deflators (which are indicated to be default values), the local expenditures for the project (input by the user as \$10,000,000) and the percentages for labor, materials and construction workers who have migrated from outside the area (which, although not indicated as such, happen in this case to be default values as well).

Then the model output is shown. The first block of numbers is mostly output from the EIFS model. Changes in direct and indirect sales, direct employment, direct income, population, demand for housing and relocating employees which are caused by the project are estimated by EIFS and displayed here.

Also provided is a summary estimate of changes in government revenues and expenditures caused by the project. This estimate is calculated from the LPFI model and is followed by a detailed breakdown of different categories of revenue and expenditure in the data block labelled "Local Public Finance Impact Analysis." Under the "Government Revenues" heading, for example, the model indicates that the

Figure 5 - EIFS/LPFI Model Impact Analysis Construction Project in Southern Illinois

construction project in southern Illinois will reduce revenue from Federal transfers to State and local governments by \$2,000, (figures are presented in thousands of dollars), reduce State and local transfers outside the region to those inside the region by \$62,000, raise sales, property and other taxes inside the region by \$21,000, and raise intra-regional charges and miscellaneous revenues by \$76,000, for a net gain to local governments in the region of \$32,000. A similar interpretation applies to the breakdown of government expenditure numbers.

The final four lines of output show a summary of public expenditures and revenues as calculated by EIFS itself. It should be noted that these totals are different from the totals provided by LPFI and are also summary figures only, not detailed breakdowns. These figures show where EIFS ends and LPFI begins and how the two models are different. EIFS estimates the economic changes induced by the proposed project. LPFI uses this information to estimate detailed changes in government expenditures and revenues. It happens that EIFS also is capable of calculating of changes in overall government revenues and expenditures in the region, but does not do so with the same level of detail as LPFI and also provides different estimates than LPFI. An analysis in one of the appendices to this report indicates that the LPFI estimates for government finances are more accurate than those provided by EIFS.

CASE 2: STAFF REDUCTION WITH SUBSTITUTE CONTRACT IN LOS ANGELES

The second case (Figure 6) analyzed by the EIFS/LPFI model is that of an example of a firm reducing its staff size and replacing their function by a contract with another firm. This is sometimes called "out-sourcing." Under this simple scenario, an existing office employing 2,500 workers (each making \$65,000 per year in salaries) is to be closed and replaced by a contract let to a local firm for \$300 million.

The analysis is similar to that offered for case study 2. Only one county - Los Angeles county - is in the ROI and in this case the "functional area" chosen is "1", i.e. the Standard EIFS forecast model to analyze a change in staffing levels rather than construction of a new facility.

Since this is a staff reduction rather than a new construction project, the model output in Figure 6 are a bit different from Figure 5. Rather than local expenditures for construction, the user had to enter the change in expenditures for local services and supplies, in this case \$300,000,000. The user also had to enter an estimate of the size of the reduction in civilian employment, namely 2,500 people, and their average income, \$65,000. All of these inputs are shown in the first block of output labelled "ECONOMIC IMPACT FORECAST SYSTEM MODEL RUN." That output block also shows the percent of affected civilian personnel expected to relocate, in this case everyone (100%).

The next block of output labelled "STANDARD EIFS MODEL FORECAST" shows the same information as shown in Figure 5, that is changes in sales volume, employment, income, population, demand for housing, relocating employees and government finances. All but the government finances estimates are provided by EIFS. The government finances figures, both total and broken down by category, are calculated by LPFI and are provided in the block below labelled "Local Public Finance Impact Analysis."

Figure 6 - EIFS/LPFI Model Impact Analysis Staff Reduction with Substitute Contract in Los Angeles

The LPFI analysis shows that a shift in civilian employment from direct employment to outsourcing with a \$300,000,000 with a local firm results in a net increase in government revenues by close to \$3 million (\$2,839,000 to be exact). What money the local governments lose through a reduction in employment is apparently made up for by the increase in income to the local firm which gained the contract and by the reduction in expenditures necessary for local services for the now displaced workers (remember, it is assumed here that 100% - all - of the affected employees will move to other jurisdictions outside the region).

One contrast worth noting here is between the EIFS estimates of government finance impact and the LPFI estimate. In this case, while LPFI finds a net gain to the local government of close to \$3 million, the EIFS model estimates a net loss of over \$6 million (\$6,192,000). While differences between the EIFS and LPFI models are not always this dramatic, this is an example of how the different equations embedded in LPFI can lead to results which would lead to decisions quite dissimilar to those based on EIFS results. As one of the appendices shows, preliminary analysis shows that LPFI generally is a better predictor of government finance impacts from local projects than EIFS.

CASE 3: NEW CORPS OF ENGINEERS OFFICE IN LOS ANGELES

The third case (Figure 7) is similar to the second case, except it is a scenario in which a new office opens (rather than closes). Here a new Corps of Engineers activity starts in the Los Angeles area whose purpose is to study, manage, and mitigate urban flooding problems. The new office has a staff of 2,500 economists, engineers, biologists, and other professional personnel. Their average annual salary is \$65,000 (i.e., cost locality). The office has been given an annual budget for operations of \$300 million, to be spent in the local community.

The basic interpretation of the output in Figure 7 can be found in the analyses of cases 1 and 2 (Figures 5 and 6). Again, what is interesting here is the difference between the EIFS estimates and the LPFI impacts, and also the distinction between the overall economic impacts of the office expansion and the more narrow effects of this expansion of local government finances. LPFI shows this \$300,000,000 office expansion to have a negative impact on government finances equal to a net reduction in net revenues of \$9,653,000. The EIFS model shows a net positive impact on government finances of \$12,018,000.

How can a major office expansion be a bad thing? That is what the LPFI model seems to be showing. The answer is that the expansion is not a bad thing for the region in economic terms. Sales volume, employment, income, population and demand for housing all increase because of the project. These newly enriched taxpayers also earn more taxable income and this new economic activity results in increased taxable transactions, resulting in increased government revenues. However, since it is assumed that all the new employees will come from outside the region (remember, "the percent of affected civilian personnel expected to relocate" is 100%), the local government is faced with 2,500 new constituents, all of whom place new demands on the government for local services, thus pushing up expenditures on these services beyond the increase in revenues caused by the new activity. Net government revenues thus decline, or at least that is what LPFI predicts.

Figure 7 - EIFS/LPFI Model Impact Analysis New Corps Office in Los Angeles

CASE 4: REUSE FUNCTION FOR CHANUTE AIR FORCE BASE

The fourth case (Figure 8) is an example of a "reuse" analysis of a proposed activity to be located at Chanutte Air Force Base in Illinois. The proposed light manufacturing facility (when operating at full capacity) is expected to employ 15,000 people with an average annual salary of \$45,000. In addition, the plant will require the expenditure of \$100 million in services and supplies to support its operations.

The basic analysis of Figure 8 is quite similar to those for the other case studies. Unlike those case studies, this one affects 12 counties and not just one or two. Also, LPFI shows that the expansion of the Chanutte Air Force Base results in a net gain in regional government revenues equal to \$1,487,000, as opposed to the net gain estimate of \$20,201,000 produced by EIFS.

One reason that this AFB expansion results in a net gain of income for local governments while the Los Angeles expansion did not is that only 50% of the affected personnel in this case are expected to come in from outside the region while in the Los Angeles case, 100% of those affected were predicted to migrate into the region. The local governments in Illinois were thus not as proportionately overwhelmed with new service demanders as the local governments in Los Angeles county. This example indicates how the LPFI model can be used to vary assumptions for regional projects to test the sensitivity of income and expenditure predictions to different assumptions about factors such as migration of people into and out of the area in response to a project. In this case, planners might want to see if net revenues are still positive when it is assumed that 100% of workforce expansion must come from outside the region. Of course, in- and out-migration is only one of many factors, such as the characteristics of the regional economies, the costs of providing public services and tax rates, which might account for differences between the Los Angeles case study and this one.

LOCAL PUBLIC FINANCE IMPACT MODEL: USER'S GUIDE AND TECHNICAL DOCUMENTATION

5. CURRENT FISCAL IMPACT ANALYSIS PROCEDURES³

Fiscal impacts are concerned with public costs and revenues. Traditionally, fiscal impact analysis has focused on the impacts of residential or nonresidential entrance into or departure from a locality. In recent years there has been considerable interest shown in the development of quantitative models for fiscal impact assessment. These models typically allow for the treatment of multiplier impacts and multi-regional (e.g., local-to-state or local-to-local) fiscal flows. The models below are described in terms of their characteristics and attributes, not in terms of what they don't do or how well they perform.

This section examines the different fiscal impact analysis (FIA) methods currently used by practitioners. First, traditional methods, as exemplified by those contained in the *Fiscal Impact Handbook* by Burchell and Listokin (1978), are discussed. This reference work remains the most widely used practical guide for conducting fiscal impact studies by consultants and local planning agencies. This is followed by an overview of more recent developments in fiscal impacts modeling. Five models are reviewed including two products of the U.S. Department of Commerce's Bureau of Economic Analysis: the Regional Input-Output Modeling System (RIMS II) and the Texas Fiscal Impact Model (TFIM). Also reviewed is the Virginia Impact Projection (VIP) Model (Johnson and Keeling, 1987), a model developed by the New Jersey Office of Economic Policy to analyze the impact of economic growth on the budgets of municipal and state governments in New Jersey (Office of Economic Policy, 1986), and a model (called EIFS) developed by the U.S. Army Construction Engineering Research Laboratory to analyze the regional economic, demographic, and fiscal impacts of military realignment actions (Huppertz and Bloomquist, 1992).

TRADITIONAL FISCAL IMPACT ANALYSIS

Burchell and Listokin (1978) outline six (6) alternative procedures for estimating the local revenue and expenditure impacts of new developments. These are: Per Capita Multiplier, Service Standard, Proportional Valuation, Case Study, Comparable City, and Employment Anticipation.⁴ All six techniques are similar in two respects. First, they may be described as single-region methods. That is, each approach examines the revenue and expenditure effects of a project on a single community in isolation. No attempt to model project-induced transfers of funds between a municipality and the state or among municipalities is made. A second characteristic common to all six methods is their lack of treatment of multiplier impacts. The reason cited for not including multiplier effects is that they are too difficult to identify and model (Burchell, Listokin, and Dolphin, 1985, p. 3). This view seems to ignore the

³The section is largely based on a discussion by Kim Bloomquist (1988).

⁴For a detailed description of these methods see Burchell, Listokin, and Dolphin (1985).

tremendous amount of research in economic base and input-output methods that has occurred during the last three decades.⁵ Moreover, others have pointed out the potential importance of secondary (or multiplier) fiscal effects on a community (Muller, 1975, p. 28).

The traditional or conventional methods described by Burchell and Listokin (1978) differ in what kinds of fiscal impacts they measure and how they measure them. Several of the methods are specialized in the measurement of fiscal impacts of residential developments, others in the analysis of nonresidential projects. Furthermore, the approach used in measuring impacts varies; some of the methods use average costing while others adopt a marginal costing approach. The table below displays the classification of these six techniques according to application and approach.

TABLE 1
Classification of Traditional FIA Methods

<u>Approach</u>	----- Application -----	
	<u>Residential</u>	<u>Nonresidential</u>
Average Costing	Per Capita Multiplier Service Standard	Proportional Valuation
Marginal Costing	Comparable City Case Study	Employment Anticipation Case Study

Of the four methods applicable for use with residential developments, the most commonly used technique is the Per Capita Multiplier method. This procedure is the least expensive to implement and inputs may be readily obtained from existing secondary sources. The Case Study method is the most expensive in terms of time and effort required, although it provides the greatest amount of detail. The Service Standard method requires less information to implement than the Case Study method, but more than Per Capita Multiplier, especially if local standards are used. The Comparable City technique requires about the same amount of information as the Service Standard method and is less often used due to the necessary assumption that growth in one city will emulate the pattern and timing of growth in other cities.

The Proportion Valuation method is the most frequently used approach for analysis of nonresidential fiscal impacts. Again, the primary reasons are simplicity and use of available secondary data for inputs. The Employment Anticipation method, described in detail in Listokin and Beaton (1983), has only been estimated for a small sample of communities in New Jersey. It does require more information than Proportional Valuation and is calibrated using econometric techniques. Finally, the Case Study approach may also be used for nonresidential projects.

⁵See Richardson (1985), for example, for a comprehensive review of this research.

Both average and marginal costing techniques may be used to project local government expenditures resulting from growth. The principal difference is that average costing assumes this relationship is linear while marginal costing allows for economies of scale and other factors which may influence the cost of providing municipal services. Generally, average costing methods are less expensive to implement. On the other hand, marginal costing techniques, while requiring greater expenditure of time and effort in data collection, should be used when there is significant excess or deficient capacity in the system of municipal services being provided. In the long run, however, the two techniques will produce similar estimates of growth impacts.

In the following subsections, two of the six traditional methods--per capita multiplier and proportional valuation--are described in greater detail. The remaining four techniques are used for less often by practitioners. Readers wishing information on the other methods should consult Burchell and Listokin (1978).

Per Capita Multiplier Method: The Per Capita Multiplier (PCM) method is a general approach for estimating the fiscal impacts of residential developments. Revenues and expenditures associated with a proposed development are estimated separately and compared to determine net impacts. Local revenues are grouped into four categories: (1) revenues associated with real property (property tax); (2) revenues associated with income (typically local income, sales, and utility taxes); (3) per capita, per pupil, or other per "population unit" revenues (e.g., state and federal education revenues); and (4) miscellaneous revenues (fees, user charges, licenses, etc.). Expenditures are classified as either operating or capital expenditures. Operating expenditures are further subdivided into education--typically the largest outlay--and noneducational services.

The PCM approach uses existing expenditure and revenue relationships to project future impacts. The underlying assumption is that current service quality, tax structure, and tax rates are to be maintained. Municipal operating expenditures are estimated by multiplying current average expenditures per capita by the project-induced change in population. New capital costs are allocated between new and existing developments. Property tax revenues are derived by applying the property tax rate to the assessed valuation of the new development. Sales tax revenues are determined by projecting retail sales and applying the tax rate. The change in local income tax revenue is calculated using the tax rate times the change in personal income. The change in state and federal aid for education is usually estimated using the number of new school-age children expected to reside in the development with the appropriate school-aid formula. Finally, miscellaneous revenues are calculated using per capita rates.

Proportional Valuation Method: The Proportional Valuation (PV) method is an average costing approach used to estimate the impact of nonresidential (industrial and commercial) developments on local costs and revenues. A two-stage process is used to assign a share of municipal costs to new nonresidential uses. First, the proportion of total municipal costs for nonresidential activities is determined. The assumption usually is made that relative real property values represent shares of municipal costs. An alternative is to use the ratio of employment to the sum of population and employment as a means of allocating municipal expenditures to business (Isard and Coughlin, 1957). The second step is to allocate a portion of these nonresidential costs to the new facility. Again, this is typically accomplished using proportional property value to employment relationships. Municipal revenues stemming from the establishment of a new commercial enterprise are estimated using the same procedure as in PCM.

Empirical studies have shown that the direct proportional assignment of municipal costs tends to greatly understate or overstate actual outlays. Thus, "refinement coefficients" have been introduced as a means of overcoming this deficiency (Burchell and Listokin, 1978). Selecting appropriate refinement coefficients imposes an additional problem for the analyst since such coefficients are likely to vary by geographic area and government unit. Therefore, the analyst may have to contend with less accurate estimates of fiscal impacts unless a substantial effort is made to collect this additional information. If this is seen as desirable, then one might simply conduct a full Case Study analysis.

RECENT FISCAL IMPACT MODELS

In recent years there has been considerable interest shown in the development of quantitative models for fiscal impact assessment. Unlike traditional or conventional fiscal impact analysis methods, these models typically allow for treatment of multiplier impacts and multiregional (e.g., local-to-state or local-to-local) revenue flows. At the same time, however, these models rely on more sophisticated estimation procedures, require a greater number of inputs, and are significantly more complex, thereby making them less understandable to the non-technician. Five of these models are only briefly described here.⁶ One model, the Economic Impact Forecast System (EIFS) Forecast Impact Model, will be used for comparative purposes later in this report.

Regional Input-Output Modeling System: In the early 1980's, the U.S. Bureau of Economic Analysis (BEA) developed the Regional Input-Output Modeling System (RIMS II) (BEA, 1981). RIMS II is used to estimate the regional economic impacts (e.g., changes in output, employment, and income) for a specific activity, such as a new manufacturing plant.

Recently, the U.S. Bureau of Economic Analysis (BEA) expanded its RIMS II program to include a fiscal impact component (Beemiller, 1987). The fiscal component to the RIMS II model makes projections for local government revenues and expenditures likely to occur in response to the socioeconomic impacts associated with a project. The expenditure impacts are estimated using linear regression techniques on cross-section data. The impacts on tax revenues (sales, personal income, and property) are estimated by applying the local tax rate to the change in the tax base. The impacts on federal and state transfer payments, other taxes, and user charges are based on the population changes induced by a project. Projections are made at the county level for study regions consisting of up to five counties and a planning horizon of up to seven years specified by the user.

Texas Fiscal Impact Model: The Texas Fiscal Impact Model (TFIM) was also developed by BEA to specifically examine state and local fiscal impacts of large-scale defense projects (Kort, Lienesch, and Ambargis, 1987). TFIM was developed specifically to examine the state and local fiscal impacts of large-scale defense projects (e.g., home-porting). Unlike RIMS II which is estimated using cross-section data, TFIM uses time-series equations to project state and local government revenues (7 categories) and expenditures (12 categories). The time-series data for the fiscal variables come from the Bureau of the Census', *Government Finances* for intercensal years and *Census of Governments* for census years.

⁶The purpose here is to note the existence and characteristics of other models, not to provide detailed explanations of how each model works. More detailed discussion of these models are given by Bloomquist (1988).

TFIM is linked to both the RIMS II and NRIES II (National-Regional Impact Evaluation System) models.⁷ RIMS II is used to determine the multiplier impacts of an initial change in local economic activity and NREIS II supplies forecasts of future economic and demographic variables which are used as explanatory variables in the fiscal model. This configuration facilitates analysis of interregional and intertemporal fiscal impacts.

Virginia Impact Projection Model: The Virginia Impact Projection (VIP) Model was developed by the Virginia Polytechnic Institute and State University (Johnson and Keeling, 1987). VIP is an econometrically estimated model based on cross-section data for the 96 counties and 45 cities of Virginia. Projections are made for eleven expenditure variables and nine revenue variables, with an emphasis on non-local aid revenue sources. Demographic variables such as labor force, population and public school enrollment also are projected.

The VIP model allows for a wide range of impact scenarios ranging from a change in the local fire protection rating through a change in the median level of education of the population. Separate versions of VIP are available for cities and counties. The decision to offer two separate models was made after empirical evidence for scale economies in the provision of services was noted (Johnson and Keeling, 1987). Thus, the model would seem to be well-suited for estimation of impacts at different spatial levels.

New Jersey Office of Economic Policy Model: The New Jersey Office of Economic Policy recently developed a fiscal impact model to assess the impact of growth along several major transportation corridors in that state (Office of Economic Policy, 1986). The purpose of the model is to determine whether municipal and state governments will realize a fiscal surplus or deficit from anticipated growth in these areas. This application is concerned with identifying the fiscal impacts associated with land use changes.

Instead of attempting to forecast impacts on individual categories of expenditures and revenues as is done in RIMS II, TFIM, and VIP, the New Jersey model only estimates total impact. While this may reduce the amount of information available to the analysts, this approach also reduces the inputs needed to operationalize the model.

Economic Impact Forecast System Forecast Impact Model: The Economic Impact Forecast System (EIFS) is a computer based economic modeling and information system developed by economists and analysts at the U.S. Army Construction Engineering Research Laboratory which supports regional economic impact analyses by planners analysts within the military and by non-military economists and social scientists. EIFS provides its users with analytical capabilities for assessing the magnitude and significance of potential socioeconomic impacts of proposed actions or projects within any county or multi-county area of the United States. The EIFS impact model contains a two-equation, local area public finance model. One equation each for expenditures and revenues.

⁷For a complete discussion of how RIMS II and NREIS II are linked, see Kort, Cartwright, and Beemiller (1986).

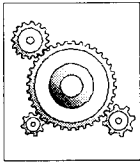

EVALUATION OF CURRENT FISCAL IMPACT ANALYSIS METHODS

Several of the procedures and models discussed above have very attractive features. The conventional or traditional fiscal impact analysis methods exhibit the virtues of low cost of implementation, greater understandability by non-economists, and current widespread application by local planners. However, they are at best measures of fiscal change, perhaps only useful for ranking project alternatives according to relative impact (i.e., project A is likely to produce greater net fiscal benefits than project B, and B greater than C, and so forth). The traditional methods have normally omitted consideration of multiplier impacts as well as multi-jurisdictional fiscal flows. The omission of multiplier effects may lead to significant undercounting of the total fiscal impacts of a project. Finally, projects that may affect both residential and nonresidential land users--such as flood control--would require the use of two separate techniques (PCM and PV, for example) to estimate fiscal impacts. PCM, by itself, is not suited for analysis of nonresidential developments because population change is used to drive the model and there is often no direct link between a nonresidential development and population change. For example, the additional jobs resulting from the creation of an industrial park may be filled by unemployed local residents.

In addition to being large and complex models, both TFIM and RIMS II rely on in-house BEA models and databases (e.g., NRIES II) for inputs. Furthermore, TFIM is estimated using time-series data which is scarce at the sub-state level. Both the Virginia Impact Projection Model and the New Jersey Office of Economic Policy Model are specifically designed for the idiosyncratic characteristics of their individual state economies and governmental systems. Adapting either of these models to more general application would require substantial investment of time and resources. The Economic Impact Forecast System offered the option of a generally available system for most planners and economists that is low cost, that does not require substantial amount of input data, and that estimates the multiplier aspects of fiscal impact analysis.

In the local public finance literature, there have been a number of theoretical studies that assume that fiscal benefits "spill over" from one area to another.⁸ These "spill overs" stem from several sources. For example, it is reasonable that residents and public officials in one community know of types and levels of public services provided in nearby or surrounding communities. Well established public finance notion indicates that administrators and other public officials, who are responsible for making local revenue and expenditure decisions, are influenced by the decisions of their counterparts in other jurisdictions, especially in communities that are nearby or that may be competitive in terms of their locational advantages or disadvantages for businesses and residents. In addition, people from surrounding communities often use the public services (such as parks, hospitals, libraries, police and fire services, etc.) that are provided by a single jurisdiction. Highways in one jurisdiction may benefit the residents of a neighboring area that travel over those roads. The effects of excellent education institutions in one region can spill over into other regions as people move and influence the variety and amounts of public services provided to residents. None of the existing readily available fiscal impact analysis methods account for these geographic interactions.

⁸See, for example, Williams (1966), Brainard and Dolbear (1967), Pauly (1970), Arnott and Grieson (1981), and Gordon (1983).

LOCAL PUBLIC FINANCE IMPACT MODEL: USER'S GUIDE AND TECHNICAL DOCUMENTation

6. TECHNICAL DOCUMENTATION FOR THE LOCAL PUBLIC FINANCE IMPACT MODEL

Recently, Case, Hines, and Rosen (1991) implemented a model of fiscal benefit spillovers which explicitly modelled the fiscal policy interdependence between states. Kelejian and Robinson (1993) investigated a model of fiscal policy interdependence of county police expenditures. The following model of local government revenues and expenditures build on the theoretical and empirical developments of Kelejian and Robinson (1993).

BASIC LOCAL PUBLIC FINANCE IMPACT MODEL

As a point of departure, we assume that people in the position of making decisions regarding the provision of and payment for the public services approach their public decision making responsibilities in an honest and forthright manner. That is, we believe that administrators and public officials try to provide the types and amounts of public services (i.e., roads, schools, hospitals, etc.) that they think their constituents want. Similarly, it is our opinion that the officials will attempt to fashion the funding strategies (i.e., bonds, taxes, etc.) necessary to pay for those services in ways that are satisfactory to their constituents (or at least, the methods that they will put up with).

In general, investments in public services normally take several years to bear fruit (schools, streets, and other facilities take time to construct and begin operations). Therefore, public officials are left with making these expenditure decisions today when the implementation of those services will not be complete until sometime later. That is, officials attempt to determine their constituents' desires today for levels of services that will occur in the future.

In addition, we assume that the decision makers are familiar and make comparisons with the types and levels of public services provided in nearby or surrounding communities. Further, we assume that this familiarity and these comparisons somehow affect the decisions concerning the types and levels of services that local public officials provide to their constituents. Similarly, we expect that public administrators and local legislators will raise revenues to provide public services, based on what the administrators and legislators think their constituents want and in comparison with the revenue burdens of neighboring areas.

We think that the above considerations will tend to make public officials "risk averse" to changes in decisions regarding funding requirements (i.e., taxes and other revenue enhancements) and expenditure levels. Also, we feel that this conservatism will cause a certain amount of inertia in the system so that adjustments over time in their funding requirements and level of expenditures will tend to be sluggish. In other words, if a local official perceives a need for more school or highway capacity, he/she will be

reluctant to embark on a major construction program with out careful consideration of his/her constituents' desires.

The public officials's predictions of his/her constituents' desired levels of revenue and expenditures are determined by what the officials know of their constituents' needs and tastes. It is reasonable to assume that the officials will determine these needs and tastes through a knowledge of their community's demographic, economic, and financial characteristics. Age and racial composition, educational attainment, income and employment opportunities, preponderance of poverty, housing preferences, and local fiscal conditions would all pay important roles in molding a public official's predictions of their constituents' needs and demands for revenues and expenditures.

The Local Public Finance Impact model is predicated on the notion that changes in the factors that affect the public officials' estimates of their constituents' demand for public services or need for revenues and that changes in their neighbors' provision of public services and revenue levels will change the levels of a community's expenditures and revenues. The following two sections generically discuss the revenue and expenditure equations of the LPFI model. The next three sections present the factors that affect expenditure revenue decisions and the empirical estimation of the model and a discussion of the model's result. Finally, a discussion of the LPFI model's performance in comparison with that of the EIFS model is presented.

LOCAL GOVERNMENT REVENUES

If R_{it} is per capita public revenues in area i at time t for some category of interest (e.g., transfers, miscellaneous charges, etc.), then we can model the above type of behavior with the following equation;

$$(R_{it} - R_{it-1}) = \alpha_r(R_{it}^d - R_{it-1}) + \rho_{r1} \bar{R}_{it}^n + \rho_{r2} \bar{R}_{it-1}^n + v_{it} \quad [1a]$$

where,

R_{it}^d is the level of per capita revenues that are predicted by local legislators and public administrators in locality i at time $t-1$ to be tolerated by their constituents during time t .

\bar{R}_{it}^n is the average per capita revenues of area i 's neighbors at time t . i indicates the locality.

$t, t-1$ are time periods (respectfully, current and previous periods).

α_r, ρ_r 's are parameters.

v_{it} is the error term in the model (administrators and legislators do not always have perfect foresight, nor are they always able to perfectly implement their programs).

The adjustment parameter, α_r , corresponding to past level of public revenues and the perception of the level of tolerance for revenues that public officials think their constituents want in the future is analogous to the "capital stock adjustment" mechanism of investment theory found in macroeconomics.⁹ α_r indicates the amount of the difference between present revenue levels and public officials' perceptions of voters' tolerance for future revenues which will be eliminated during a given period). It seems intuitive that α_r is positive but less than one (i.e., $0 < \alpha_r < 1$).

⁹The capital stock adjustment principle is explained by James Gapinski (1982, pp. 177-182).

\mathbf{R}_{it}^n and $\bar{\mathbf{R}}_{it-1}^n$ are both considered in equation [1a] to account for the possibility of both contemporaneous and lagged response feedbacks vis-a-vis neighboring localities (ρ_{r1} and ρ_{r2}). If changes in public revenue decisions are "very" sluggish then this suggests that ρ_{r1} is zero. We also expect that $|\rho_{r1}| < 1$ and $|\rho_{r2}| < 1$ because of spatial stability issues.¹⁰

Local public officials' perceptions in time $t-1$ of their voters' desired revenue levels in time t are formed based on what the local administrators and legislators know about their communities in time $t-1$; for example, we assume that

$$\mathbf{R}_{it}^d = \mathbf{X}_{rit-1} \mathbf{B}_r, \quad [2a]$$

where \mathbf{X}_{rit-1} is a vector of variables (or set of information) for area i in time $t-1$ that influence the predictions by legislators of constituents's tolerance for public revenues, and \mathbf{B}_r is a vector of parameters that contain the weights that legislators place on the variables.¹¹

As it is configured above, our model (equations [1a] and [2a]) can not be directly estimated. However, if [2a] is substituted into [1a] and then the terms are rearranged, we get

$$\mathbf{R}_{it} = (1-\alpha_r)\mathbf{R}_{it-1} + \mathbf{X}_{rit-1}(\alpha_r\mathbf{B}_r) + \rho_{r1}\bar{\mathbf{R}}_{it}^n + \rho_{r2}\bar{\mathbf{R}}_{it-1}^n + \mathbf{v}_{it}. \quad [3a]$$

Because $0 < \alpha_r < 1$, the coefficient of the lagged revenue variable, \mathbf{R}_{it-1} , in [3a], namely $1-\alpha_r$, is clearly between zero and one: $0 < 1-\alpha_r < 1$.

Equation [3a] is specified for five (5) categories of revenue sources.

- Federal transfers
- State and local transfers
- Local taxes
- Charges and miscellaneous revenues
- Utility, liquor store, and insurance trust revenues

All revenue data were expressed in per capita terms with the exception of local taxes. Local taxes were estimated in terms of tax rates (i.e., relative to local personal income). See Appendix C for the definition of the revenue variables.

LOCAL GOVERNMENT EXPENDITURES

If \mathbf{E}_{it} is per capita public expenditures in area i at time t for some category of interest (e.g., police, education, administration, etc.), then we can model the above type of behavior with the following equation;

$$(\mathbf{E}_{it} - \mathbf{E}_{it-1}) = \alpha_e(\mathbf{E}_{it}^d - \mathbf{E}_{it-1}) + \rho_{e1}\bar{\mathbf{E}}_{it}^n + \rho_{e2}\bar{\mathbf{E}}_{it-1}^n + \mathbf{u}_{it} \quad [1b]$$

¹⁰Spatial stability issues are discussed by Robert Haining (1990, pp. 66-69).

¹¹The vector \mathbf{X}_{rit-1} is likely to contain a similar set of explanatory variables as is contained in \mathbf{X}_{eit-1} (defined above).

where,

E_{it}^d is the level of per capita expenditures that are predicted by local legislators and public administrators in locality i at time $t-1$ to be desired by their constituents during time t .

\bar{E}_{it}^n is the average per capita expenditure of area i 's neighbors at time t .

i indicates the locality.

$t, t-1$ are time periods (respectfully, current and previous periods).

α_e, ρ_e 's are parameters.

u_{it} is the error term in the model (administrators and legislators do not always have perfect foresight, nor are they always able to perfectly implement their programs).

The adjustment parameter, α_e , corresponds to past level of public expenditures and the perception of the level of the expenditures that public officials think their constituents will desire in the future. Here, α_e indicates the amount of the difference between present expenditures and public officials' perceptions of voters' desires for future expenditures which will be eliminated during a given period). It seems intuitive that α_e is positive but less than one (i.e., $0 < \alpha_e < 1$).

\bar{E}_{it}^n and \bar{E}_{it-1}^n are both considered in equation [1b] to account for the possibility of both contemporaneous and lagged response feedbacks vis-a-vis neighboring localities (ρ_{e1} and ρ_{e2}). If changes in public expenditure decisions are "very" sluggish then this suggests that ρ_{e1} is zero. Again, we also expect that $|\rho_{e1}| < 1$ and $|\rho_{e2}| < 1$ because of spatial stability issues.

Local public officials' perceptions in time $t-1$ of their voters' desired expenditure levels in time t are formed based on what the administrators and legislators know about their communities in time $t-1$; for example, we assume that

$$E_{it}^d = X_{cit-1} B_e, \quad [2b]$$

where X_{cit-1} is a vector of variables (or set of information) for area i in time $t-1$ that influence the predictions by legislators of constituents's desires for public expenditures, and B_e is a vector of parameters that contain the weights that legislators place on the variables.

As it is configured above, our model (equations [1b] and [2b]) can not be directly estimated. However, if [2b] is substituted into [1b] and then the terms are rearranged, we get

$$E_{it} = (1-\alpha_e)E_{it-1} + X_{cit-1}(\alpha_e B_e) + \rho_{e1} \bar{E}_{it}^n + \rho_{e2} \bar{E}_{it-1}^n + u_{it}. \quad [3b]$$

Because $0 < \alpha_e < 1$, the coefficient of the lagged expenditure variable, E_{it-1} , in [3b], namely $1-\alpha_e$, is clearly between zero and one: $0 < 1-\alpha_e < 1$.

Equation [3b] is specified for ten (10) categories of expenditures.

- Education expenditures
- Health and hospital expenditures

- Transportation expenditures
- Police protection and corrections expenditures
- Fire protection expenditures
- Natural resources, parks, and recreation expenditures
- Public welfare, housing, and community development expenditures
- Sewerage and sanitation expenditures
- Government finance, administration, and general expenditures plus interest on the debt
- Utility, liquor store, and insurance trust expenditures

All expenditure data are expressed in per capita terms with the exception of education expenditures. Education expenditures are expressed in per student terms. See Appendix C for the definition of the expenditure variables.

FACTORS AFFECTING EXPENDITURE AND REVENUE DECISIONS

The vectors containing the factors that influence the predictions by local administrators' and legislators' presumptions concerning the tolerances for revenues and the desires for expenditures (i.e., X_{rit-1} and X_{eit-1} , respectively) was taken to be a variety of demographic, economic, and financial variables for counties in the United States. These data include,¹²

Demographic variables:

- Population
- Median age of population
- Percent of population that is school-aged: 3-18
- Percent of population over age 60
- Percent of population that is black
- Percent of population that is white
- Percent of population that finished high school
- Percent of population that ever attended college
- Percent of population over age 15 that are divorced or separated
- Percent of population living in urban area
- Population density

Economic variables:

- Income per capita
- Median housing value
- Percent of population living in rental housing
- Percent of housing that is vacant
- Unemployment rate
- Percent of working-aged population unemployed 15 weeks or more

¹²See Appendix B for definitions and sources.

- Percent of families with no workers
- Percent of families below the poverty level with children aged 6-17

Financial variables:

- Federal transfers per capita
- State and local transfers per capita
- Local taxes as a percent of personal income
- Total local revenues

Generally, the same set of demographic and economic variables were contained in both the X_{rit-1} and the X_{eit-1} vectors. These variables were included to measure the respective communities' tolerances of local revenues and desires for local expenditures, on which the local officials base their predictions. The vector for revenues, X_{rit-1} , contained the financial variables for transfers (federal, state, and local) and local taxes rates. The vector for expenditures, X_{eit-1} , contained the financial variables for total local revenues.

EMPIRICAL ESTIMATION

Sample and Data: Counties are used as the unit of observation because they constitute a convenient aggregate of local governments. In total, there are 3,092 counties in the country where data for all of the dependent and explanatory variables are available. The time periods of the analysis covered 1982 and 1987 (the latest two reported Censuses of Governments). All monetary values are deflated to the base year of 1982 using the personal consumption expenditure (PCE) deflator from the U.S. Bureau of Economic Analysis (BEA).

The dependent variables for the estimated equations were,

Revenue Variables	Expenditure Variables	
FEDERAL XFERS	EDUCATION	PARKS & REC
STATE XFERS	HLTH & HOSP	WELFARE & HOUS
TAX RATE	TRANSPORT	SANITATION
CHG & MISC	POLICE PROT	FIN & ADM
UTILITY	FIRE PROT	UTILITY

Each estimated equation contained one or more of the explanatory variables listed below.

LAG DEP	YOUNG	RENTP
M CUR DEP	OLD	VACANT
M LAG DEP	BLACK	UNEMP
FED TRN	WHITE	HARD
S&L TRN	HIGH	IDLE
TAX RATE	COLLEGE	POVERTY
INPP82	DIVORCE	URBAN
POP82	HVAL	DENSITY
MEDAGE		

The **LAG DEP**, **M CUR DEP**, and **M LAG DEP** variables are, respectively, the lagged dependent variable (for 1982), the neighbors' current average value of the dependent variable (for 1987), and the neighbors' lagged average value of the dependent variable (for 1982). In addition to the explanatory variables given above, a set of state-specific "dummy" variables was used in each estimated equation to determine significant state-level differences in the estimated revenue and expenditure relationships.

An interesting feature of this model is the explicit consideration of the revenue and expenditure decisions in one area being influenced by the revenue and expenditure decisions of neighboring communities. For the purposes of estimation, the neighbors of one county are defined to be any counties whose population centers are within fifty (50) miles of the subject county.

Estimation Procedures: The theoretical basis and an explanation of the procedures used to estimate equations [3a] and [3b] for each of the revenue source and expenditure categories are provided by Kelejian and Robinson (1993).

The logic of the model is that the revenue and expenditure decisions in each area are partly determined by the revenue and expenditure decisions in neighboring areas. Generally, it was assumed that neighbors' current average level of revenues or expenditures (the variable **M CUR DEP**) would be a significant explanatory variable for each estimated equation. If so, then a variable such as \bar{R}_{it}^n in equation [3a] or \bar{E}_{it}^n in equation [3b] must be determined by the dependent variable, namely R_{it} and E_{it} (respectively). The reason being, that the i^{th} area is itself a neighbor to its neighboring areas. This implies that equations [3a] and [3b] can not be consistently estimated by ordinary least squares (OLS) procedures. Consequently, a two-stage least squares (2SLS) procedure was used to estimate each equation. The considered set of instrumental variables for each estimated equation contained corresponding neighbors' average value for each of the explanatory variables used in the estimated equation plus an additional common set of variables. The additional common set of variables included the neighbors' average values for the following variables:

INPP82	COLLEGE	UNEMP
MEDAGE	MARRIAGE	FLABOR
YOUNG	DIVORCE	POVERTY
OLD	VACANT	HARD
TEENT	RENTP	IDLE
BLACK	HVAL	URBAN
WHITE	RVAL	DENSITY
HIGH		

If the coefficient of the **M CUR DEP** (i.e., ρ_{r1} or ρ_{e1}) was not significantly different from zero (i.e., by examining their estimated t-values), then the **M CUR DEP** variable was dropped as an explanatory variable and the equation was re-estimated using OLS procedures. **Discussion of Model Results:** Equations [3a] and [3b] were estimated for each of the for five revenue sources and the ten expenditure categories described above. The results of the estimation process (described above) for the

revenue and expenditure categories are shown in Tables 2 and 3.¹³ For the sake of brevity, detailed discussion of each equation will not be undertaken here. What follows is a discussion of several of interesting comparisons and contrasts between the equations.

The first feature of the estimated equations is the consideration of the "sluggishness" parameter. That is, the significance and value of the estimated coefficients of the **M CUR DEP** variable (i.e., ρ_{r1} or ρ_{e1}). It was noted above that if local public revenue and expenditure decision makers were "sluggish," then these coefficients should not be statistically significant different from zero. This was the case for all sources of revenues, except for tax rates, and for six categories of expenditures (expenditures for police protection, fire protection, welfare and housing, sanitation, finance and administration, and utilities). Interestingly, the other categories of revenues and expenditures, which have estimated values of ρ_{r1} and ρ_{e1} that are significantly different from zero, are ones for which there tends to be inter-jurisdictional competition and rivalry (for tax rates and expenditures for education, health and hospitals, transportation, and parks and recreation). It is very common, for example, to see a community's low tax rates or its superior educational and recreational facilities advertised in newspapers and other media.

The second feature of this model is the explicit consideration of the revenue and expenditure decisions in one area being influenced by the revenue and expenditure decisions of neighboring communities. This spatial feedback affect is measured by the effects of the revenue and expenditure decisions in neighboring communities (i.e., through the coefficients ρ_{r1} , ρ_{r2} , ρ_{e1} , and ρ_{e2}). Decisions on tax rates and on expenditures for education, health and hospitals, transportation, police protection, and parks and recreation appear to exhibit significant spatial feedback effects. In no case were any of the estimated spatial feedback effects greater than one or less than minus one.¹⁴

Third, across the equations for all revenue sources and for all expenditure categories, the estimated coefficients for the lagged dependent variables (i.e., $1-\alpha_r$ and $1-\alpha_e$) positive, less than one, and statistically significant different from zero. This means, as was expected above, that the estimated "stock adjustment" parameters (i.e., α_r 's and α_e 's) are positive and less than one. This means that local public officials will try to eliminate the difference between present revenues and expenditures and their perceptions of their voters' desires for future revenues and expenditures.

Overall, the equations appear to reasonably capture the behavior of local public officials with regard to the revenue and expenditure decisions. Comparing the differences between the actual 1987 per capita revenue and expenditure levels and those predicted by the model, the equations are able to explain from 40 to 83 percent (%) of the variance in the revenue levels and from 31 to 79 percent of the expenditure levels throughout the entire country (using R^2 adjusted for degrees of freedom as a measure

¹³The results in Tables 2 and 3 do not include the coefficients for the state dummy variables and their standard errors or their t-values. Complete estimation results (including for the state dummy variables) and the Time Series Processor (TSP) program that generated the results are provided in Appendix D.

¹⁴This is a stability condition than has been noted by many researchers in the spatial econometrics literature; see, for example, Robert Haining (1990, pp. 66-69) for a discussion of spatial stability issues.

for comparison). In terms of revenues, the model is best at explaining state transfers, tax rates, and utility revenues ($R^2 \geq .8$). For expenditures, the model is best at explaining education, police protection, fire protection, and welfare and housing expenditures ($R^2 \geq .7$). However, the model explains health and hospital, transportation, and utilities expenditures reasonably well (i.e., $.5 < R^2 < .7$)

EVALUATING THE LPFI MODEL PERFORMANCE

The local area public finance impact model developed within this report has been evaluated econometrically above. This, however, provides little in the way of performance evaluation under a variety of conditions. For example, how well does the model perform within each state of the country? Does the model predict revenues and expenditures better within metropolitan counties or in non-metropolitan counties? Does it matter which way the geography is delineated, by state or by economic area? Or, how much better does the model predict in comparison with another local public finance model?

Measuring Prediction Error:¹⁵ In the previous section, the R^2 statistic adjusted for degrees of freedom was used to evaluate the overall goodness of fit for the model. One way of evaluating the accuracy or performance of the model is to compare the model's predictions against actual historical data in terms of percentage errors.

The *percentage error* (%ERR) for revenue or expenditure category i in county j at time t is

$$\%ERR_{ijt} = 100 \times \frac{PRE_{ijt} - ACT_{ijt}}{ACT_{ijt}} \quad [4]$$

where PRE_{ijt} is the model's prediction of revenue or expenditure category i in county j at time t and ACT_{ijt} is the historical level of revenue or expenditure category i in county j at time t . Then for any level of geographic aggregation, the *mean prediction error* for revenue and expenditure category i at time t can be computed as

$$MPE_{it} = \sum_j \frac{\%ERR_{ijt}}{n_j}$$

where n_j is the number of counties in the subject geographic aggregation.

The percentage error and the mean percentage error has a serious flaw. That is, one county may have a 2% error and another county may have a -2% error. When these counties are combined, their percentage errors will cancel out. The *mean absolute percentage error* (MAPE) corrects for this problem because it is the average of the absolute percentage error. The absolute percentage error of a 2% or a -2% error is still a 2% error. The MAPE for revenue or expenditure category i at time t is

$$MAPE_{it} = \frac{1}{n_j} \sum_j 100 \times \frac{|PRE_{ijt} - ACT_{ijt}|}{ACT_{ijt}}$$

¹⁵This discussion is based largely on that found in Treyz (1993, pp. 57-59).

The **MAPE** shows the average percentage error for a grouping of counties, but it does not indicate whether there is a bias in the predictions.¹⁶

An Alternative Model:¹⁷ A common method of evaluating regional economic models is to compare a proposed model (i.e., the model developed herein) with a currently used model. This model, called the Economic Impact Forecast System (**EIFS**) impact forecast model, acts as both an information source and as an analytical tool. EIFS allows its users to "define" an economic region of influence (ROI) by simply identifying the counties (typing in the county names) to be analyzed. Once the ROI is defined, the system aggregates the data, calculates "multipliers" and other variables used in the actual models, and is ready for user input data.

Figure 9 illustrates the general model structure found in all of the EIFS impact forecast models. This figure is useful because it not only shows the relationship that actions and projects have with their regional economies, but it also summarizes the interrelationships among the various economic and social sectors of the community.

Proposed actions and projects usually involve changes in personnel, wages and salaries, and procurement for materials and supplies. In EIFS, personnel are classified as either civilian or military. Factors are applied to capture the unique nature of the residential and consumption behavior of each of these groups. The actions and projects lead to changes in the demand for goods and services either from the personnel spending their incomes to support their families or from purchases to carry out project activities. Initial expenditures for goods and services are called the *direct project effects*. In turn, direct project effects lead to further changes in the demand for productive requirements through the technical relationships that exist between the requirements needed to produce the goods and services and the commodities that are produced. Subsequent impacts that result from the initial round of spending are called the *indirect project effects*.

According to Figure 9, the EIFS impact forecast model estimates changes in county and local government revenues are estimated as a consequence of changes in local income and population. Changes in county and local government expenditures are derived in response to changes in local employment and population. The specific equations that the EIFS model uses to estimate local government revenues and expenditures are,

$$\Delta GR = \Delta Y_{tr} \times \frac{\text{ownsource}}{y_{res}} + \Delta POP \times \frac{\text{xfers}}{\text{totpop}} \quad [4a]$$

$$\Delta GE = (\Delta POP + \Delta EM_t) \times \frac{\text{totexp}}{\text{totpop} + \text{totemp}} \quad [4b]$$

¹⁶That is, whether the predictions tend to be too high or too low.

¹⁷The alternative model described here is documented by Huppertz and Bloomquist (1992).

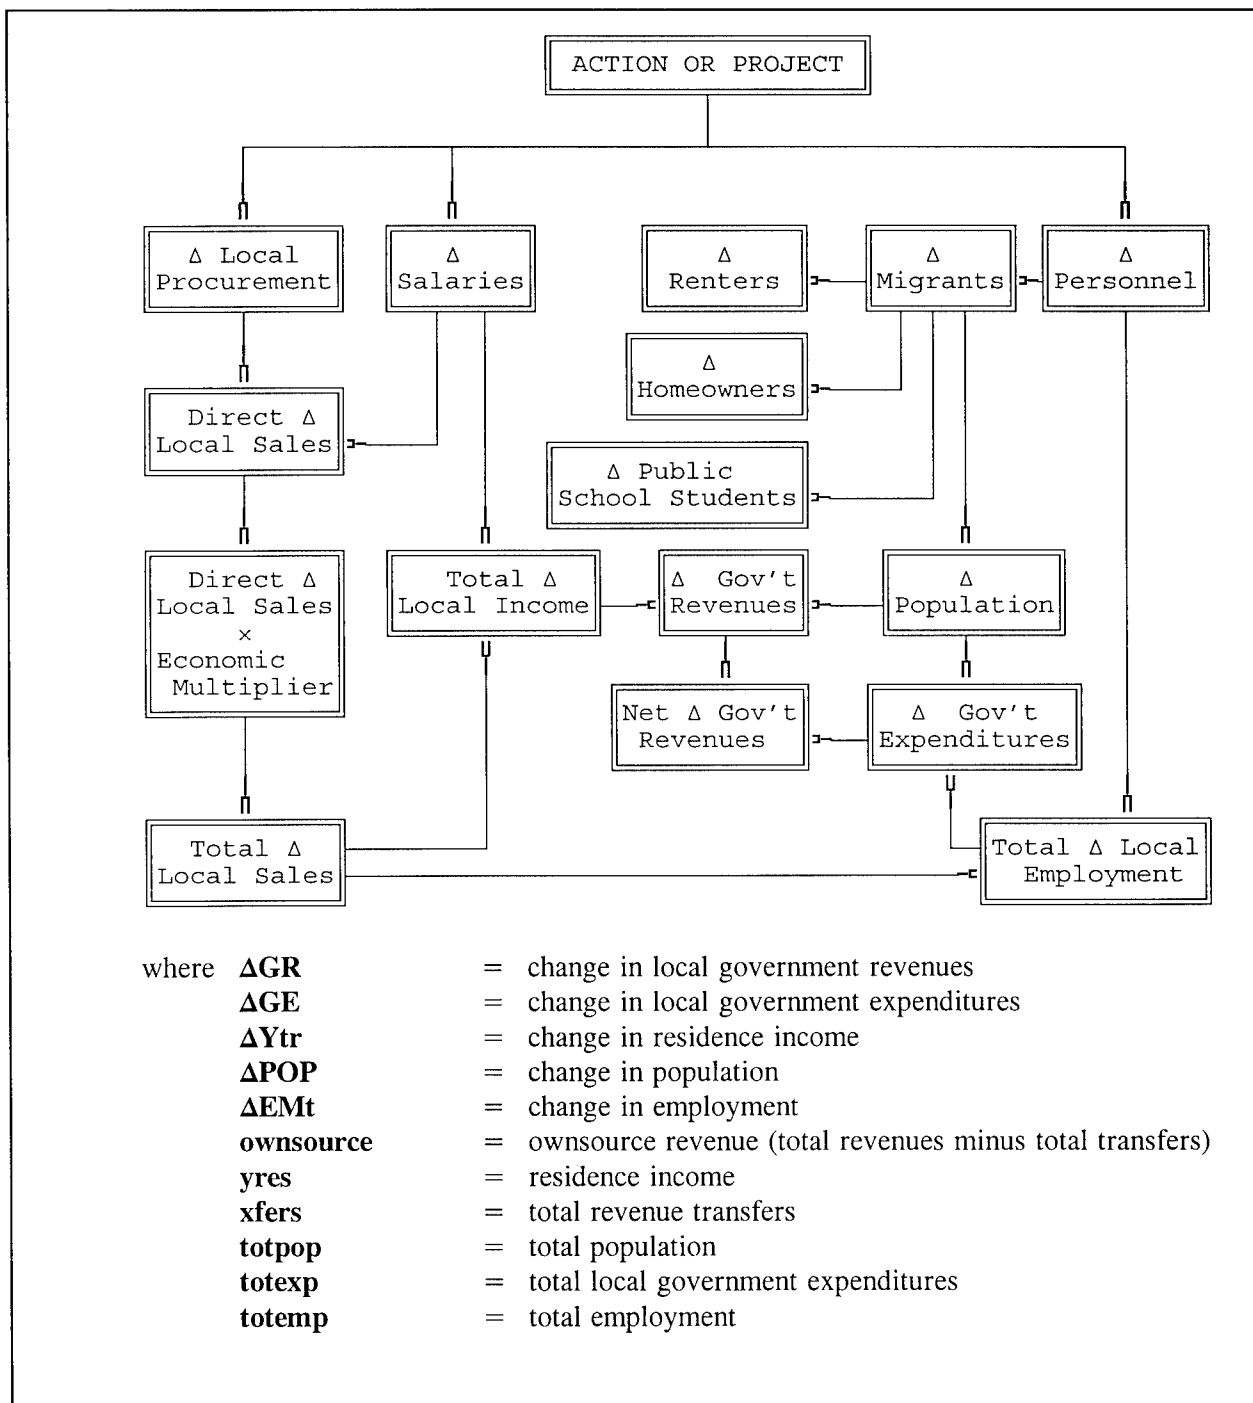

FIGURE 9: Generic EIFS Impact Forecast Model

Data on historical public revenues and expenditures are from the Census of Governments and historical income, population, and employment data are from the Bureau of Economic Analysis. Both source are defined for the same year. The changes in income, population, and employment are generated in the EIFS impact forecast model as a result of some proposed action or project (see Figure 9 above).

Compatibility of LPFI and EIFS Models: There are only a few compatibility issues that inhibit direct comparisons between the revenue and expenditure forecasts of the Local Public Finance Impact model and the Economic Impact Forecast System impact forecast model. Both models use the same sources of base data; both models can estimate local public finance impacts for the same time periods and for the same levels of geography.

The major overriding issues of compatibility are impact detail and per capita impacts vs level impacts. LPFI estimates public finance impacts in terms of individual categories of revenues and expenditures, while EIFS estimates total revenue and expenditure impacts. Also, LPFI estimates revenue and expenditure impacts in per capita terms,¹⁸ while EIFS estimates levels of revenues and expenditures.

Two steps were taken to ensure the compatibility of the two models' estimates of public finance impacts. First, because the LPFI model estimates its impacts for 1987 in terms of what public officials know in 1982, the EIFS model parameters were computed using 1982 base data. In addition, the income, population, and employment changes were computed between 1982 and 1987. Second, the predicted results of the LPFI model by revenue and expenditure category were converted to levels, aggregated to total revenues and total expenditures, and then converted back to a per capita basis. The EIFS predictions were converted to a per capita basis.

Prediction Error Analysis in Total: MAPE statistics were computed for per capita total revenue and total expenditure predictions for both the EIFS and LPFI models. These MAPE statistics were first calculated in total for the United States and for counties within metropolitan statistical areas and for those counties outside metro areas. The summary MAPE statistics are shown below in Table 4.¹⁹ Note, the EIFS model revenue predictions are about 100 percent (%) higher than those of the LPFI model and the expenditure impacts are about one-third higher. Also, the disparities between the revenue and expenditure MAPE statistics are far greater for the EIFS model as the disparities for the LPFI model.

¹⁸Except for tax rates and education expenditures per student.

¹⁹The large sizes of the average absolute percentage error is due to the fact that a number of counties in the United States changed their revenue and expenditure habits rather significantly during the period 1982 and 1987. These significant changes in local public finance behaviors are due in part to the shifting funding and expenditure responsibilities from the Federal level to the state and local levels. In addition, there has been a recent trend in "privatizing" local services (i.e., selling local public services for private ventures) or ceasing certain services (e.g., closing local public hospitals where large regional facilities are available).

Table 4
Mean Absolute Percentage Error Analysis: Total
United States Per Capita Local Government
Revenues and Expenditures

	Current Eifs Model		LPFI Model	
	Rev	Exp	Rev	Exp
Total	23.2	15.3	11.8	11.9
Metro	20.8	14.0	10.5	10.0
Non-Metro	24.0	15.7	12.2	12.5

Prediction Error Analysis by Geographic Area: Similar analyses were carried out for states, BEA economic areas, and for the metropolitan and non-metropolitan portions of states (see, respectively, Tables 5, 6, and 7). The overwhelming conclusion is that the performance comparison between the public revenue and expenditure predictions of the LPFI and the EIFS models that was noted for the United States as a whole also holds for states, BEA economic areas, and metro/non-metro areas of states. That is, the MAPE statistics for the LPFI model are substantially lower than for the EIFS model.

LOCAL PUBLIC FINANCE IMPACT MODEL: USER'S GUIDE AND TECHNICAL DOCUMENTATION

APPENDIX A REGION OF INFLUENCE DEFINITION

The assessment of socioeconomic impacts resulting from actions and projects can be one of the more controversial issues related to the realignment or closure of an installation. The economic and social well-being of a local community can be dependent upon the activities of the installation, and disruptions to the status quo become politically charged and emotion-laden. Of the many factors that are necessary to implement a socioeconomic impact analysis, probably one of the most challenged issues is the definition of the geographic region of influence (ROI).

The justifications of most study areas often are ignored--perhaps because the region is predefined (e.g., for an analysis of the fiscal impact of a tax cut within the State of Alabama) or maybe because the regions were the only available units of observation for a "cross-section" study. Unfortunately, few universally accepted rules are available to help an analyst choose a study area. Thus, the regional setting for an impact analysis is usually somewhat subjective or arbitrary. Careful thought and judgement should always be exercised when delineating regions.

CONCEPTUAL CONSIDERATIONS

Other than a geographic aggregate, what is a region? There are as many answers to this question as there are people who use geographic settings for their analyses. Such diversity of opinion is due mostly to the different uses of spatial aggregates.²⁰ Most regional and urban analysts performing socioeconomic impact analysis prefer the functional area concept for defining study regions.²¹ Regions defined in this way explicitly consider the economic linkages and spatial dimensions between and among the residential population and businesses located in the geographic area. In other words, commuting and trading patterns are of prime concern. This type of region is often called "nodal" because:

²⁰Two other methods of defining regions are frequently used. First, regions are sometimes delineated along administrative or political boundaries (e.g., the State of Alabama). It is often claimed that since the institutional framework within which economic and social policies are designed and implemented is of overriding importance, then the geographic unit of analysis should coincide with the same administrative or political boundaries. Second, homogeneity of one form or another can be used to justify some regions. For example, one can envision coal mining regions, river-basin regions, air pollution regions, or even German-speaking areas. What binds these areas is usually some common physical, economic, social, or statistical characteristic.

²¹The concept of a functional economic area (FEA) appears attributable to Karl Fox (Fox and Kuman, 1965).

... the region is perceived as being composed of heterogeneous nodes of different size (cities, towns, villages and sparsely populated rural areas) that are linked together functionally. These functional links can be identified through observation of flows of people, factors, goods and communications (Richardson, 1979, p.21).

An examination of a map shows that population and businesses are not spread evenly over space, but are concentrated at specific locations called "agglomerations." The factors that generate these agglomerations are varied; e.g., transportation advantages (such as the confluence of several rivers), resource deposits, factor endowments, local infrastructure (such good schools and public transportation facilities), climate, and even proximity to firms that supply needed production requirements or provide ready markets.

Chalmers and Anderson (1977) discuss an important relationship between the size of a region and subsequent socioeconomic impacts. A larger area usually implies larger populations, greater factor endowments, richer resource deposits, and more readily available productive supplies. All these attributes make for more integrated and more diverse economic structures that, in turn, lead to larger socioeconomic impacts. On the other hand, larger regions also tend to dilute the strength of socioeconomic impacts, which means that the impacts tend to be relatively smaller.

PRACTICAL CONSIDERATIONS

Beyond the general conceptual guidelines for defining regions, there is little formal advice about defining regions. With respect to economic and fiscal impact analysis, it is probably obvious that a region should be the geographic area in which the significant economic and social consequences of a project occur. However an analyst decides to delineate a study area, the decision will have to be based on his/her considered judgement; possibly from past experience or, perhaps, based on specific knowledge of the area under consideration. As a practical matter, another important issue is determining the smallest geographic unit for which relevant data are available. For the most part, counties provide these data.²²

The definition of the affected region must include all the ingredients of self-sustaining region-local businesses, local governments, and individuals. The region must reflect the limits of the economic activity associated with the affected population. This is not an easy definition to obtain and numerous "simplistic" attempts at a standard methodology have failed. Through experience, however, it has become obvious that the following considerations must be included in the definition of the ROI:

- The *residence patterns* of the affected personnel determine where they are likely to spend their salaries. There may be records of addresses of personnel which can serve as a means to document this consideration, or there may be an established perception among area residents regarding where the personnel at the affected installation live, and it is generally correct.

²²Although some data are available at the census tract level (e.g., population and income) which could possibly be used to delineate regions, the data needed to analyze economic impacts are most readily available only at the county level, unless one is willing to conduct expensive and time-consuming surveys.

- The availability of local *shopping opportunities* is also a factor in the regional definition. The location of new malls or other popular shopping opportunities can dictate an expansion in the region of influence if no comparable opportunities exist in the immediate vicinity.
- The "*journey-to-work*" time for employees often dictates part of the regional definition. On average, a journey-to-work time of one hour is considered a maximum criteria, however, some regions in the country are characterized by higher travel times for a typical commute. It is affected significantly by the quality of the transportation network, the availability of mass transit, and what impacts are felt during "rush hour" peaks.
- Local *customs and culture* often dictate the boundaries of the ROI. Long versus short commute patterns, willingness to approach the "inner city," the sense of local community, and other factors often lead to seeming inconsistencies in the regional definitions. These are unfortunately, hard to address factors, but are nonetheless a fact of life which must enter into the analysis process and the definition of the ROI.

None of the considerations above can be used exclusively to define ROIs for all socioeconomic studies. It is necessary that all these considerations enter into the ROI definition process. This often requires input from local personnel in addition to analysis of secondary data (maps, data, etc).

RECOMMENDATIONS

For the purposes of procedural recommendations, one should think of defining an ROI as a process consisting of three steps (Chalmers and Anderson, 1977):

- Define the direct impact area,
- Define the direct/indirect impact area, and
- Perform geographic sensitivity analysis.

The direct impact area is the region where the personnel and their dependents reside and do the majority of their shopping. This is where the strongest socioeconomic impacts of the proposed action or project will occur. The direct/indirect impact area is the geographic region where the great majority of the economic effects induced by the spending behavior of the affect personnel, their dependents, and any expenditures for services and supplies is expected to occur. Note, the direct/indirect impact area is the ROI that is used for the socioeconomic impact analysis and for the subsequent the significance evaluation. Although step one is relatively straight forward, assuming that the residential patterns of the affected personnel are readily available, steps two and three may have to be performed several times during a socioeconomic impact analysis.

Step 1: Define the Direct Impact Area

The direct impact area is determined by the residential patterns of the personnel affected by the proposed action. In the case of plant closures, the residential patterns of the present staff is probably adequate the purposes here. Care should be taken to accurately locate the residences of as many of the personnel as possible; e.g., 95 percent or more. This information should be available from a personnel office or from project records.

In the case of military installation expansions, the size and personnel composition of the proposed action compared with the present personnel population may require further consideration of local residential opportunities, beyond the residential patterns of the present post personnel staff, in order to properly define the direct impact area. For example, if an installation is located in a predominantly rural area, with limited housing and local educational facilities, and the proposed action is to double the present staff at the installation with a different mission (such as adding a new major headquarters activity at an installation with a historical operations or distribution mission), then in order to determine the residential patterns of the new personnel may require a significant evaluation of adequacy of local housing opportunities and infrastructure requirements.

If the residential patterns of the personnel are not available, or if they are not applicable to the impact scenario under study, then one could consider using a secondary data method of defining the direct impact area that appeals to a labor force concept of an area.²³ For example, consult a map and, using a convenient radius, specify the geographic area surrounding the action or project within which employees are likely to reside and shop. In other words, how far do the affected personnel commute to work? As an example, from a recent survey of Air Force personnel, Gunther (1982) found that fewer than one percent (1%) of Air Force personnel reside further than 50 miles from their installations.

Step 2: Define the Direct/Indirect Impact Area

The direct/indirect impact area is the area where the spending and responding due to the proposed action or project, implied by the economic processes, are most likely to occur. This is, in fact, the same as the ROI. Defining the direct/indirect impact area is not as straightforward as determining the just the direct impact area, because it requires has more elements of subjective judgement. As a practical matter, the direct/indirect impact area includes the direct impact area, as well as those communities in the surrounding areas where significant effects are likely to occur because of local interrelationships between consumers, merchants, and industrial suppliers.

In most cases, this means that the direct/indirect impact area (and the ROI itself) will be larger than the primary impact area. How much larger will vary depending on the overall region being studied. The more sparsely settled a study area, the larger the market area of the wholesale-retail center with the consequence that the ROI (direct/indirect impact area) could contain large areas not already included in the direct impact area. In more densely settled parts of the country, less difference will exist in the geographic boundaries of the two areas and they may even coincide (Chalmers and Anderson, 1977, p. 40).

Considering the importance of trade activity in the economic process, the direct/indirect impact area should not only contain the direct impact area, but also any nearby trade and service centers and their market areas as well (*shopping opportunities*). Other, difficult to address factors can also play an important role in defining the direct/indirect impact area; for example, commuting patterns, sense of "community," and attractiveness of the inner city (*customs and culture*). Local officials and other knowledgeable individuals may have to consulted to adequately consider these factors. In addition,

²³Please note, this should be the "last resort" method of defining a direct impact area. Always use the residential patterns of personnel if they are available and are applicable.

natural boundaries (such as rivers, mountain ranges, major highways) will need to be evaluated to properly define the direct/indirect impact area.

Metropolitan Statistical Areas (MSA) boundaries may delineate the direct/indirect impact area. MSAs include a central city or cities and the surrounding territory that is economically and socially dominated by the city. Since the MSA is a major regional trade and service center, it is often an appropriate choice for a direct/indirect impact area.²⁴ If the direct impact area does not fall within the limits of any MSA, the analyst must decide which, if any MSA to include in the direct/indirect impact area. Choosing the nearest MSA to the direct impact area may not be appropriate, as that MSA may not be the trade and service center that most attracts the shoppers from the direct impact area. The Economic Impact Forecast System (EIFS) contains the geographic definitions of MSAs and Bureau of Economic Analysis (BEA) Economic Areas within the United States, so that they can be accessed directly when entering EIFS.²⁵

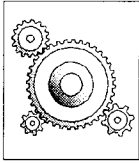

Step 3: Perform Geographic Sensitivity Analyses

Examine the selected ROI thoroughly. A proposed project may affect areas outside the boundaries a proposed region, such as a county or Metropolitan Statistical Area (MSA). Use as much knowledge of the area as can be gleaned from maps, data, local officials, and other socioeconomic impact analyses to determine the areas that can be affected by the action in question. Run the LPFI/EIFS models several times, varying the boundaries of the study area, to see how the socioeconomic impacts change as the geographic area changes. Keep these runs in your records for future reference.

²⁴The current standards for the establishment and definition of MSAs were adopted in January 1980. They provide that each MSA must include at least one city with 50,000 or more inhabitants, or a Census Bureau defined urbanized area of at least 50,000 inhabitants and a total MSA population of at least 100,000 (75,000 in New England). MSAs include as a central county(ies) the county in which the central city is located, and adjacent counties, if any, with at least 50 percent of their population in the urbanized area. Additional outlying counties are included if they meet specified requirements of commuting to the central counties and of metropolitan character (such as population density and percent urban).

²⁵BEA Economic Areas offers alternative direct/indirect impact area definitions that provides complete geographic coverage of the United States (BEA, 1977). These areas, 183 in all, are "nodal" functional area delineated to facilitate regional economic analysis. Each area consists of an economic node--an MSA or similar area, that serves as a center of economic activity--and the surrounding counties that are economically related to the center. To the extent possible, each area includes the place of work and place of residence of is labor force.

LOCAL PUBLIC FINANCE IMPACT MODEL: USER'S GUIDE AND TECHNICAL DOCUMENTATION

APPENDIX B **VARIABLE AND DATA SOURCES USED IN THE LPFI MODEL**

Revenue Variables (1982 and 1987)

FEDERAL XFERS	Federal transfers per capita (3&4)
STATE XFERS	State and local transfers per capita (3&4)
TAX RATE	Local taxes as a percent of personal income (3&4)
CHG & MISC	Charges and miscellaneous revenue per capita (3&4)
UTILITY	Utility, liquor store, and insurance trust revenue per capita (3&4)

Expenditure Variables (1982 and 1987)

EDUCATION	Education expenditures per student (1,3,4)
HLTH & HOSP	Health and hospital expenditures per capita (3&4)
TRANSPORT	Transportation expenditures per capita (3&4)
POLICE PROT	Police protection and corrections expenditures per capita (3&4)
FIRE PROT	Fire protection expenditures per capita (3&4)
PARKS & REC	Natural resources, parks, and recreation expenditures per capita (3)
WELFARE & HOUS	Public welfare, housing, and community development expenditures per capita (3&4)
SANITATION	Sewerage and sanitation expenditures per capita (3&4)
FIN & ADM	Government finance, administration, general, and debt interest expenditures per capita (3&4)
UTILITY	Utility, liquor store, and insurance trust expenditures per capita (3&4)

Explanatory Variables

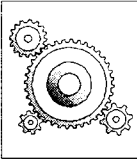

LAG DEP	1982	Dependent variable (2)
M CUR DEP	1987	Neighbors' average dependent variable (3)
M LAG DEP	1982	Neighbors' average dependent variable (2)
FED TRN	1982	Federal transfers per capita (2&4)
S&L TRN	1982	State and local transfers per capita (2&4)
TAX RATE	1982	Local taxes as a percent of personal income (2&4)
INPP82	1982	Income per capita (4)
POP82	1982	Population (4)
MEDAGE	1980	Median age of population (1)
YOUNG	1980	Percent of population that is school-aged: 3-18 (1)
OLD	1980	Percent of population over age 60 (1)
TEENT	1980	Percent of population that are teens (1)
BLACK	1980	Percent of population that is black (1)
WHITE	1980	Percent of population that is white (1)
HIGH	1980	Percent of population that finished high school (1)
COLLEGE	1980	Percent of population that ever attended college (1)
MARRIAGE	1980	Percent of population over age 15 that are married (1)

DIVORCE	1980	Percent of population over age 15 that are divorced or separated (1)
HVAL	1980	Median housing value (1)
RVAL	1980	Median rental value (1)
RENTP	1980	Percent of population living in rental housing (1)
VACANT	1980	Percent of housing that is vacant (1)
UNEMP	1980	Unemployment rate (1)
FLABOR	1980	Percent of females in labor force (1)
HARD	1979	Percent of working-aged population unemployed 15 weeks or more (1)
IDLE	1979	Percent of families with no workers (1)
POVERTY	1980	Percent of families below the poverty level with children aged 6-17 (1)
URBAN	1980	Percent of population living in urban area (1)
DENSITY	1982	Population density (4)

All monetary values were deflated to a base year of 1982 using the PCE deflator from the U.S. Bureau of Economic Analysis.

LOCAL PUBLIC FINANCE IMPACT MODEL: USER'S GUIDE AND TECHNICAL DOCUMENTATION

APPENDIX C DEFINITIONS OF GOVERNMENT FINANCE DATA²⁶

General Revenue.

All government revenue except utility revenue, liquor store revenue, and employee-retirement and other insurance trust revenue. The basis of distinction is not the fund or administration unit receiving particular amounts, but rather the nature of the revenue source concerned.

Intergovernment Revenue.

Amounts received from other governments as fiscal aid in the form of shared revenues and grants-in-aid, as reimbursements for performance of general government functions and specific services for the paying government (e.g., care for prisoners or contractual research) or in lieu of taxes. Excludes amounts received from other governments for sale of property, commodities, and utility services. All intergovernmental revenue is classified as general revenue.

Federal Transfers.

Intergovernmental revenue received by a government directly from Federal Government. For local governments excludes Federal aid channeled through state governments.

State and Local Transfers.

Fiscal aid revenue that allows the receiving government unrestricted use as a function or purpose.

Local Taxes.

Compulsory contributions exacted by a government for public purposes, except employee and employer assessments for retirement and social insurance purposes, which are classified as insurance trust revenue. All tax revenue is classified as general revenue and comprises amounts received (including interest and penalties but excluding protested amounts and refunds) from all taxes imposed by a government. Note that local government tax revenue excludes any amounts from shares of state-imposed and collected taxes, which are classified as Intergovernment Revenue.

²⁶Selected definitions from *Attachment 5 (Definitions of Selected Terms)* of the *Census of Governments, 1987: Finance Statistics (Technical Documentation)*. Washington, DC: U.S. Department of Commerce, Bureau of the Census (1990).

Corporate Net Income Taxes. Taxes on net income of corporations and unincorporated businesses (when taxed separately from individual income). Include distinctively imposed net income taxes on special kinds of corporations (e.g., financial institutions).

Death and Gift Taxes. Taxes imposed on the transfer of property at death, in contemplation of death, or as a gift.

Individual Income Taxes. Taxes on individuals measured by net income and taxes distinctively imposed on special types of income (e.g., interest, dividends, income from intangibles, etc.).

License Taxes. Taxes enacted (either for revenue raising or for regulation) as a condition to the exercise of a business or non-business privilege, at a flat rate or measured by such bases as capital stock, capital surplus, number of business units, or capacity. Excludes taxes measured directly by transactions, gross or net income, or value of property except those which only nominal rates apply. "License" based on these latter measures, other than those at nominal rates, are classified according to the measure concerned. Includes "fees" related to licensing activities--automobile inspection, professional examinations, and licenses, etc.--as well as license taxes producing substantial revenues.

Property Taxes. Taxes conditioned on ownership of property and measured by its value. Includes general property taxes related to property as a whole, real and personal, tangible or intangible, whether taxes at a single rate or classified rates, and taxes on selected types of property, such as motor vehicles or certain or all intangibles.

Sales and Gross Receipts Taxes. Taxes, including "licenses" at more than nominal rates, based on volume or value of transfers of goods or services; upon gross receipts or gross income; and related taxes based on use, storage, production (other than severance of natural resources), importation, or consumption of goods. Dealer discounts of "commissions" allowed to merchants for collection of taxes from consumers are excluded.

General Sales or Gross Receipts Taxes. Sales or gross receipts taxes which are applicable with only specified exceptions to all types of goods and services, or all gross income, whether at a single rate or at classified rates. Taxes imposed distinctively upon sales or gross receipts from selected commodities, services, or businesses are reported separately under category listed below.

Selective Sales and Gross Receipts Taxes. Sales and gross receipts taxes imposed on particular commodities or services or gross receipts or particular businesses, separately and apart from the application of general sales and gross receipts taxes. Specific taxes on items such as alcoholic beverages or tobacco products are examples.

Charges and Miscellaneous Revenue.

Amounts received from the public for performance of specific services benefiting the person charged, and from sales of commodities and services except by government utilities and liquor stores. Includes fees, assessments, and other reimbursements for current services, rents and sales derived from commodities or services furnished incident to the performance of particular

functions, gross income of commercial activities, and the like. Excludes amounts received from other governments (see *Intergovernmental Revenue*) and interdepartmental charges and transfers. Current charges are distinguished from license taxes, which related to privileges granted by the government or regulatory measures for the protection of the public.

Special Assessments. Compulsory contributions collected from owners of property benefited by special public improvements (street paving, sidewalks, sewer lines, etc.) to defray the cost of such improvements (either directly or through payment of debt service on indebtedness incurred to finance the improvements) and apportioned according to the assumed benefits to the property affected by the improvements.

Utility, Liquor Store, and Insurance Trust Revenue.

Insurance Trust System. A government-administered program for employee retirement and social insurance protection relating to unemployment compensation, workmen's compensation, Old Age, Survivors', Disability, and Health Insurance, and the like.

Insurance Trust Revenue. Comprises amounts from contributions required of employers and employees for financing these social insurance programs, and earnings on assets of such systems.

Liquor Store Revenue. Amounts received from sale of liquor by government liquor stores and other revenues from government liquor store operations. Excludes any taxes collected by government liquor monopoly systems.

Utility Revenue. Revenue from sale of utility commodities and services to the public and to other governments. Does not include amounts from sales to the parent government. Also excludes income from utility fund investments and from other nonoperating properties (treated as general revenue). Any revenue from taxes, special assessments, and intergovernmental aid is classified as general revenue, not utility revenue.

General Expenditure.

All government expenditure other than the specifically enumerated kinds of expenditure classified as utility expenditure, liquor stores expenditure, and employee-retirement insurance trust expenditure.

Education Expenditures.

Provision or support of schools and facilities for elementary and secondary, higher and other education, and libraries. *Elementary and Secondary Education* includes the provision of public kindergarten through high school education by state and local governments. It encompasses instructional, support, and auxiliary services (school lunch, student activities, and community services) offered by public school systems. Revenues and expenditures for enterprise activities are included on a gross basis. *Higher Education* consists of all state and local institutions of higher education. Excluded are agricultural experiment stations and agricultural extension services (included under *Natural Resources*), university-operated hospitals (included under Hospitals), and scholarship and fellowship payments (included under *Other Education*). *Other*

Education includes all Federal Government educational activities with the exception of service academies (which are classified as part of *National Defense and International Relations*), state government and administrative supervision of elementary and secondary and higher education, scholarship and fellowship payments, aid to private schools, and support of special schools for deaf, blind, and other handicapped persons. *Libraries* consist of the establishment and operation of public libraries and support of privately operated libraries (excluding those operated as part of a school system, primarily for the benefit of students and teachers, and law libraries).

Health and Hospital Expenditures.

Health. Out-patient health services, other than hospital care, including: public health administration; research and education; categorical health programs; treatment and immunization clinics; nursing; environmental health activities such as air and water pollution control; ambulance service if provided separately from fire protection services; and other general public health activities such as mosquito abatement. School health services provided by health agencies (rather than school agencies) are included here. Sewage treatment operations are classified under *Sewerage*.

Hospitals. Financing, construction, acquisition, maintenance or operation of hospital facilities, provision of hospital care, and support of public or private hospitals. Includes expenditures by public hospitals under welfare programs for medical assistance such as medicaid. However, see *Public Welfare* concerning vendor payments under welfare programs.

Transportation Expenditures.

Comprises the functions of *Highways*, *Air Transportation*, *Parking Facilities*, *Water Transport and Terminals*, and *Transit Subsidies*.

Air Transportation. Construction, maintenance, operation, and support of airport facilities.

Highways. Construction, maintenance, and operation of highways, streets, and related structures, including toll highways, bridges, tunnels, ferries, street lighting, and snow and ice removal. However, highway policing and traffic control are classed under *Police Protection*.

Parking Facilities. Construction, purchase, maintenance, and operation of public-use parking lots, garages, parking meters, and other distinctive parking facilities on a commercial basis. Applies only to local governments.

Transit Subsidies. Payments in support of subway, bus, surface rail and street railroad, and other passenger transportation systems, including public support of a private utility or railroad and intergovernmental subsidy payments. Excludes amounts paid by a parent government to its dependent transit utility. Also see under *Utility*.

Water Transport and Terminals. Construction, maintenance, operation, and support of canals and other waterways, harbors, docks, wharves, and related marine terminal facilities.

Police Protection and Corrections Expenditures.

Correction. Confinement and correction of adults and minors convicted of offenses against the law, and pardon, probation, and parole activities.

Police Protection. Preservation of law and order and traffic safety. Includes police patrols and communications, crime prevention activities, detention and custody of persons awaiting trial, traffic safety, and vehicular inspection.

Fire Protection Expenditures.

Fire fighting organization and auxiliary services; fire inspection and investigation; support of volunteer fire forces; and other fire prevention activities. Includes cost of fire fighting facilities, such as fire hydrants and water, furnished by other agencies of the government.

Natural Resources, Parks, and Recreation Expenditures.

Natural Resources. Conservation, promotion, and development of natural resources, such as soil, water, forests, minerals, and wildlife. Includes irrigation, drainage, flood control, forestry and forest protection, soil reclamation, soil and water conservation, fish and game programs, and agricultural fairs. For the Federal Government, includes agricultural experiment stations and extension services, farm price stabilization programs, farm insurance and credit activities, and multipurpose power and reclamation projects.

Parks and Recreation. Provision and support of recreational and cultural-scientific facilities and activities including golf courses, playfields, playgrounds, public beaches, swimming pools, tennis courts, parks, auditoriums, stadiums, auto camps, recreation piers, botanical gardens, galleries, museums, and zoos. Also includes building and operation of convention centers and exhibition halls.

Public Welfare, Housing, and Community Development Expenditures.

Housing and Community Development. Construction and operation of housing and redevelopment projects, and other activities to promote or aid housing and community development.

Public Welfare. Support of and assistance to needy persons contingent upon their need. Excludes pensions to former employees and other benefits not contingent on need. Expenditures under this heading include *Cash Assistance* paid to needy persons under the Federal categorical programs (Supplemental Security Income and Age Assistance Aid to Families With Dependent Children) and under any other welfare programs; *Vendor Payments* made directly to private purveyors for medical care, burials, and other commodities and services provided under welfare programs; and provision and operation by the government of *Welfare Institutions*. *Other Public Welfare* includes payments to other governments for welfare purposes, amounts for administration, support of private welfare agencies, and other public welfare services. Health and Hospital services including those under public welfare programs like Medicaid, provided

directly by the government through its own hospitals and health agencies, and any payments to other governments for such purposes are classed under those functional headings rather than here.

Sewerage and Sanitation Expenditures.

Sewerage. Provision of sanitary and storm sewers and sewage disposal facilities and services, and payments to other governments for such purposes.

Sanitation. Street cleaning, solid waste collection and disposal, and provision of sanitary landfills. Sanitary engineering, smoke regulation, and other health activities are classified under *Health*.

Government Finance, Administration, General, and Debt Interest Expenditures.

Financial Administration. Officials and agencies concerned with tax assessment and collection, accounting, auditing, budgeting, purchasing, custody of funds, and other finance activities.

Government Administration. Comprises to functions of Financial Administration, Judicial and Legal, and General Public Buildings; and activities of the governing body, office of the chief executive, and central staff services and agencies concerned with personnel administration, recording, planning, zoning, and the like.

Interest Expenditure. Amounts paid for the use of borrowed money. Interest on utility debt is included in *Utility Expenditure*.

Utility, Liquor Store, and Insurance Trust Expenditures.

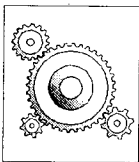

Insurance Trust Expenditure. Corresponds with the character and object category, *Insurance Benefits and Repayments*, and comprises only cash payments to beneficiaries (including withdrawals of contributions). These categories exclude costs of administering insurance trust systems, which are classed as general expenditure. Insurance trust revenue and expenditure do not include any contributions to government to a system it administers. Any amounts paid by a government as employer contributions to an insurance trust system administered by another government are classed as general expenditure for current operation, and as insurance trust revenue of the particular system and receiving government.

Insurance Benefits and Repayments. Social insurance payments to beneficiaries, employee-retirement annuities and other benefits, and withdrawals of insurance or employee-retirement contributions. Includes only amounts paid to beneficiaries; administrative expenditure for such activities are classified as *Current Operation*.

Liquor Store Expenditures. Expenditures for purchase of liquor for resale and provision and operation of liquor stores. Excludes expenditure for law enforcement and licensing activities carried out in conjunction with liquor store operations.

Utility Expenditures. Expenditure for construction of utility facilities or equipment, for production and distribution of utility commodities and services (except those furnished to parent government), and for interest on utility debt. Does not include expenditure in connection with administration of utility debt and investments (treated as general expenditure) and the cost of providing services to the parent government (such costs, when identifiable, are treated as expenditure for the function served).

Utility Expenditures Per Capita

Method of estimation = Ordinary Least Squares

Dependent variable: EX711

Number of observations: 3052

Current sample: 1 to 69, 71 to 80, 82 to 174, 176 to 477, 479 to 548, 550 to 958, 960 to 974, 976 to 1016, 1018 to 1078, 1080 to 1282, 1284 to 1621, 1623 to 1640, 1643 to 1689, 1691 to 1695, 1698 to 1743, 1745 to 1780, 1782 to 1804, 1806 to 2313, 2315 to 2348, 2350 to 2525, 2527 to 2588, 2590 to 2632, 2634 to 2636, 2638 to 2652, 2654 to 2698, 2700 to 2802, 2804 to 2807, 2809 to 2809, 2811 to 2821, 2823 to 2823, 2825 to 2829, 2831 to 2837, 2839 to 2846, 2849 to 2855, 2857 to 2859, 2861 to 2862, 2864 to 2868, 2870 to 3092

Mean of dependent variable = 151.164

Std. dev. of dependent var. = 410.937

Sum of squared residuals = .176354E+09

Variance of residuals = 58823.8

Std. error of regression = 242.536

R-squared = .657713

Adjusted R-squared = .651661

Durbin-Watson statistic = 2.06371

F-statistic (zero slopes) = 108.693

Schwarz Bayes. Info. Crit. = 11.1064

Log of likelihood function = -21062.4

13. ABSTRACT (Maximum 200 words) This report documents the development and implementation of a model to estimate the effects on local public revenue and expenditures which would be expected to stem from the construction and operation of an infrastructure facility (such as a lock and dam or a highway). To accomplish this purpose reliably, and to be of the most use to the relevant audience of local decisionmakers, the model was specified to have certain characteristics. This report summarizes the LPFI Model, its general characteristics, and its use. The report includes specific user instructions for the access and use of the FIFS/LPFI model combination. Four hypothetical case studies are provided. The traditional or conventional methods of computing fiscal (i.e., revenue and expenditure) impacts by planners are reviewed, and several available, competing fiscal impact models are discussed and evaluated. Finally, the report provides technical documentation concerning the LPFI model's logic, econometric structure, statistical estimation methodology, and performance evaluation.
